SUMMARY

In this work we present an analysis concerning the mathematical formulation of the general problem of the dynamic loading of the human head. In the proposed analysis the system is assumed to constitute of a stratified spherical medium and a methodology is developed for the study of the dynamic behaviour of the human head. The response of the human head (displacement field and pressure) is investigated when a Dirac force in space and time is applied on it. The role of various parameters entering the dynamic characteristics of the system is extensively discussed.

1. INTRODUCTION

Several researchers have proposed models to study brain injuries due to external causes such as those resulting from car accidents. The human head-neck system is a very complicated structure and various geometrical and material approximations have been used in the modeling studies.

Landkof and Goldsmith [9] performed an analytical and experimental study involving non-destructive, axisymmetric impact on a fluid-filled shell constrained by a viscoelastic artificial neck. Hickling and Wenner [10] developed a mathematical model using three-dimensional equations of linear viscoelasticity for the brain and the skull to predict the response of a human head to axisymmetric impact.

In previous communications we have extensively discussed the dynamic characteristics of the human head-neck system. We have studied simple systems [11-12] and more complicated ones which combine both geometry aspects [13-14] and material behavior of the brain and skull matter [15-16]. In Refs. 17 and 18 we have investigated the effect of the human neck support. In the above mentioned papers the role of the various parameters of the system on the dynamic characteristics (eigenfrequency and damping coefficients spectra, eigenfunctions) was investigated. The mathematical analysis was based on the expansion of the solution in terms of the Navier eigenvectors and the use of arguments from complex analysis and complicated numerical schemes.

In this work the system under consideration is assumed to constitute a stratified spherical medium. A number of models can be deduced from the general case, after making assumptions for the number of the spherical layers as well as their substance.
Consequently all the models simulating human brain system that have been adopted in previous works, can be studied under a stimulus state, in a uniform and deducible manner. More specifically, three models are described under stimulus state.

- the single elastic isotropic and homogeneous elastic skull
- the elastic skull filled with inviscid and irrotational fluid
- the two elastic spheres model

The methodology followed in the present work includes determination of the dynamic characteristics (eigenfrequencies and eigenvectors) for all the systems [11-18] and use of the proposed method to compute the displacement fields when a Dirac force in space and time is applied on it.

2. PROBLEM FORMULATION

The system under consideration is shown in Fig. 1 and consists of $n$ spherical layers simulating the several regions of the human - brain system. According to the assumptions adopted in previous works concerning the physical characteristics of the several components of the system, every spherical layer of the model is assumed to be filled with an isotropic elastic material or with an inviscid and irrotational fluid of specific properties resembling the real situation. The exterior layer stands for the skull of the system and is considered, naturally, to be an elastic region. The well - posedness of the problem requires the satisfaction of suitable boundary conditions on the discontinuity surfaces of the system. As mentioned above the number and nature of the several components vary with the particular model under consideration and depend, of course, on the physical parameters whose involvement to the dynamic characteristics of the system, is studied in priority.

The main purpose of our analysis is the determination of the response of the system when a Dirac force, in space and time, is applied on it. More precisely, we suppose that the system is subjected to the external force $F(r,t) = F_r \delta(r - r_f) \delta(t)$, per unit mass, where $F_r$ is an arbitrary vector, $r_f$ is an arbitrary point of the region $V_f$ and $\delta(\cdot)$ is the Dirac's $\delta$ - function. It is noticed here that response of the system to more general external forces can be deduced easily from the response to the Dirac force, which constitutes the Green function of the stimulus problem. In addition, the position vector $r_f$ can be arbitrarily chosen, but its selection depends on the nature of the external force. Consequently, if we study the influence of the blood pressure due to cardiac pulses, $r_f$ has to be selected near the central spherical region, but if we are
interested in responses to external stimuli, $r_j$ must be placed very near the external surface $S_n$.

![Problem Geometry and Coordinate System](image)

**Figure 1:** Problem Geometry and Coordinate System

In order to study the kinematic behavior of the system, we are going to determine the displacement field of every particular region.

More precisely, if the region $V_i$ is an elastic one then the motion of this region is characterised by the displacement field $\mathbf{u}^{(i)}(\mathbf{r}, t)$ satisfying the time-dependent non-homogeneous equation of elasticity,

$$
\mu_i \nabla^2 \mathbf{u}^{(i)}(\mathbf{r}, t) + (\lambda_i + \mu_i) \nabla (\nabla \cdot \mathbf{u}^{(i)}(\mathbf{r}, t)) + \rho_i \delta^{(i,j)} F_0 \delta(\mathbf{r} - \mathbf{r}_j) \delta(t) = \rho_i \frac{\partial^2 \mathbf{u}^{(i)}(\mathbf{r}, t)}{\partial t^2}
$$

where $\mu_i$, $\lambda_i$ are Lamé's constants, $\rho_i$ is the density of the region $V_i$ and $\nabla$ is the del operator. In addition $\delta^{(i,j)}$ is equal to 1 only if $i = j$ which means that $r_j$ belongs to the region $V_i$, otherwise is equal to zero and repetition of a subscript does not mean summation with respect to it.

If the region $V_i$ is occupied by an inviscid and irrotational fluid of density $\rho_i$ and sound speed $c_i$, then the displacement field is obtained through the velocity potential satisfying
\[ \nabla^2 \Phi^{(i)}(\mathbf{r}, t) = \frac{1}{c_i^2} \frac{\partial^2 \Phi^{(i)}(\mathbf{r}, t)}{\partial t^2}. \]  

(2)

More precisely, the pressure and displacement fields are connected to the velocity potential through the equations

\[ P^{(i)}(\mathbf{r}, t) = -\rho_i \frac{\partial \Phi^{(i)}(\mathbf{r}, t)}{\partial t}. \]  

(3)

\[ \rho_i \ddot{u}^{(i)}(\mathbf{r}, t) = \rho_i \delta^{(i,j)} F \delta(\mathbf{r} - \mathbf{r}_f) \delta(t) - \nabla P^{(i)}(\mathbf{r}, t). \]  

(4)

We apply Fourier transform analysis to the problem defining

\[ \tilde{u}^{(i)}(\mathbf{r}, \omega) = \int_{-\infty}^{+\infty} u^{(i)}(\mathbf{r}, t) e^{i\omega t} dt. \]  

(5)

\[ \tilde{\Phi}^{(i)}(\mathbf{r}, \omega) = \int_{-\infty}^{+\infty} \Phi^{(i)}(\mathbf{r}, t) e^{i\omega t} dt. \]  

(6)

\[ \tilde{P}^{(i)}(\mathbf{r}, \omega) = \int_{-\infty}^{+\infty} P^{(i)}(\mathbf{r}, t) e^{i\omega t} dt. \]  

(7)

We suppress, for simplicity, the dependence of previously transformed functions on their argument \( \omega \) and taking advantage of Fourier transform properties we get equations involving the transformed functions from the equations governing the initial fields.

For every elastic region \( V_i \) we obtain

\[ \mu_i \nabla^2 \tilde{u}^{(i)}(\mathbf{r}) + (\lambda_i + \mu_i) \nabla(\nabla \cdot \tilde{u}^{(i)}(\mathbf{r})) + \rho_i \omega^2 \tilde{u}^{(i)}(\mathbf{r}) = -\rho_i \delta^{(i,j)} F \delta(\mathbf{r} - \mathbf{r}_f), \]  

(8)

while in any region \( V_f \) filled with fluid we obtain

\[ \nabla^2 \tilde{\Phi}^{(i)}(\mathbf{r}) + \frac{\omega^2}{c_i^2} \tilde{\Phi}^{(i)}(\mathbf{r}) = 0 \]  

(9)
\[ \hat{P}^{(i)}(r) = i\rho_i \partial \Phi^{(i)}(r) \]  

(10)

\[ u^{(i)}(r) = -\frac{1}{i\omega} \nabla \Phi^{(i)}(r) - \frac{1}{\omega^2} \delta^{(i,j)} F_0 \delta (r - r_f) . \]  

(11)

Uniform handling of the several components of the system requires the introduction of dimensionless variables.

In this framework, the velocities \( c_{p, j} = \sqrt{\frac{\lambda_i + 2\mu_i}{\rho_i}} \), \( c_{s, j} = \sqrt{\frac{\mu_i}{\rho_i}} \) which characterise completely the elastic properties of the elastic medium \( V_i \) give place to \( c'_{p, j} = \frac{c_{p, j}}{c_{p, n}} \), \( c'_{s, j} = \frac{c_{s, j}}{c_{p, n}} \). Similarly, sound speed \( c_i \) in every fluid region \( V_i \) gives place to \( c' = \frac{c_i}{c_{p, n}} \).

In addition, the density \( \rho_i \) in every region \( V_i \) is replaced by the dimensionless density \( \rho' = \frac{\rho_i}{\rho_n} \).

Finally, we define the dimensionless quantities

\[ r' = \frac{r}{\alpha}, \quad \Omega = \frac{\omega \alpha}{c_{p, n}}, \quad \nabla' = \alpha \nabla, \quad (\alpha = r_s), \]

and the equations (8) - (11) in nondimensionalised form become

\[ c_{s, i}^2 \nabla'^2 \hat{u}^{(i)}(r') + (c_{p, i}^2 - c_{s, i}^2) \nabla' \nabla' \hat{u}^{(i)}(r') + \Omega^2 \hat{u}^{(i)}(r') = -\frac{\delta^{(i,j)}}{c_{p, n}} F_0 \frac{\alpha}{\Omega^2} \delta (r' - r'_f) \]  

(12)

\[ \nabla'^2 \hat{\Phi}^{(i)}(r') + \frac{\Omega^2}{c_i^2} \hat{\Phi}^{(i)}(r') = 0 \]  

(13)

\[ \hat{P}^{(i)}(r') = i\Omega \rho' \frac{1}{c_{s, i}^2} \hat{\Phi}^{(i)}(r') \]  

(14)

\[ \hat{u}^{(i)}(r') = \frac{i}{\Omega} \nabla' \hat{\Phi}^{(i)}(r') - \frac{\delta^{(i,j)}}{\Omega^2 \frac{\alpha}{c_{p, n}}} F_0 \delta (r' - r'_f) \]  

(15)
where \( \Phi^{(i)}(\mathbf{r}') \rightarrow "1" \tilde{\Phi}^{(i)}(\mathbf{r}') \) is a dimensionless quantity and "1" has measure unity.

Applying \( \nabla_i^2 \) on equation (15) and using equation (13) we obtain

\[
c_i^2 \nabla^2 \hat{u}^{(i)}(\mathbf{r}') + \Omega^2 \hat{u}^{(i)}(\mathbf{r}') = -\delta^{(i,j)} \frac{F_{j\alpha}}{c_{p,n}^2} \delta(\mathbf{r}' - \mathbf{r}'_f). \tag{16}
\]

Comparing (12) and (16), we see that it is possible to express in an uniform way the equations governing the displacement fields \( \hat{u}^{(i)}(\mathbf{r}') \) after defining in a trivial manner, \( c_{p,i}' = c_{s,i}' = c_i' \) in case where \( V_i \) is a region occupied by fluid.

Then

\[
c_{s,i}' \nabla^2 \hat{u}^{(i)}(\mathbf{r}') + (c_{p,i}' - c_{s,i}') \nabla' (\nabla \hat{u}^{(i)}(\mathbf{r}')) + \Omega^2 \hat{u}^{(i)}(\mathbf{r}') = -\delta^{(i,j)} \frac{\alpha}{c_{p,n}^2} F_{j\alpha} \delta(\mathbf{r}' - \mathbf{r}'_f), \tag{17}
\]

\( \forall \ i = 0,1,2,\ldots,n. \)

Equations (17) must be accompanied by the suitable boundary conditions. More precisely, the exterior surface \( S_{\alpha} \) is stress free, fact which is reflected in the condition \( T \hat{u}_{\alpha}(\mathbf{r}')|_{r=\alpha} = 0 \), where \( T \) is the surface traction operator [11].

Every surface \( S_i \) separating two elastic media must support equal displacement and stress fields from the two sides. In addition, every surface separating an elastic medium from a fluid filled one, must support equal displacement fields while the elastic stress field must be normal to the surface and compensate the fluid pressure. Finally two consecutive fluid regions apply to their discontinuity surface equal displacements and pressures.

Denoting uniformly

\[
\hat{u}(\mathbf{r}') = \hat{u}^{(i)}(\mathbf{r}'), \text{ for } \mathbf{r}' \in V_i \\
c_{s,i}'(\mathbf{r}') = c_{s,i}', \text{ for } \mathbf{r}' \in V_i \\
c_{p,i}'(\mathbf{r}') = c_{p,i}', \text{ for } \mathbf{r}' \in V_i \tag{18}
\]
the equation governing the displacement field can be written through only one equation with non-constant coefficients, that is

\[ c'(r')^2 \nabla^2 \tilde{u}(r') + \left[ c'(r')^2 - c'_r(r')^3 \right] \nabla \left( \nabla \cdot \tilde{u}(r') \right) + \Omega^2 \tilde{u}(r') = -\frac{F \alpha}{c_p^2} \delta(r' - r'_f), \quad r' \in V \]

(19)

Equation (19) accompanied with the above mentioned boundary conditions is a well-posed non-homogeneous boundary value problem.

Its solvability reduces to the corresponding homogeneous problem. More precisely, let us consider the boundary value problem consisting of the equation

\[ c'(r')^2 \nabla^2 \phi(r') + \left[ c'(r')^2 - c'_r(r')^3 \right] \nabla \left( \nabla \cdot \phi(r') \right) + \lambda^2 \phi(r') = 0, \quad r' \in V \]

(20)

and the same set of the boundary conditions satisfied by the solution of the non-homogeneous problem. But this is exactly the problem studied in previous works [11-18], which were referred to specific selections of geometrical and physical structures but all of them concerned the homogeneous boundary problem. Every model is provided with a sequence \( \Omega^k_n \) of eigenvalues and a sequence of the corresponding eigenvectors \( \tilde{u}^{n,k}_{m}(r'), \quad r' \in V, \quad n = 1, 2, ..., \quad |m| \leq n; \quad k = 1, 2, 3, ... \) where the pair \((n,m)\) identifies the specific polar and azimuthal dependence of the eigenstate, while \(k\) enumerates the possible eigenstates belonging to the same state \((n,m)\).

Generalised Sturm - Liouville theory guarantees that the set of functions \( \tilde{u}^n_{m}(r') \) constitutes a complete orthogonal set of functions in the space of square integrable functions in \( V \). Orthogonality can be deduced by suitable application of Green's type theorem in space \( V \), after using original Green's formulae for the fluid filled regions, Betti's formulae for the elastic ones and exploiting the boundary conditions satisfied by these solutions.

Orthogonality is expressed through the equation

\[ \int \tilde{u}^{n,k}_{m}(r') \cdot \tilde{u}^{n',k'}_{m'}(r') dr' = 0, \quad n \neq n' \quad \text{or} \quad m \neq m' \quad \text{or} \quad k \neq k'. \]

(21)
Completeness of \( \hat{u}^{m,k}_n (r') \) permits the following representation of the solution \( \hat{u}(r') \) of the non-homogeneous problem

\[
\hat{u}(r') = \sum_{n,m,k} \delta_n^{m,k}(r'_f) \hat{u}^{m,k}_n (r'),
\]

where summation extends over all possible values of indices \( n, m, k \), \( \delta_n^{m,k}(r'_f) \) are the coefficients to be determined in order for \( \hat{u}(r') \) to be found and of course these coefficients depend on the location of the impact.

Introducing (22) in (19), we find that

\[
\sum_{n,m,k} \delta_n^{m,k}(r'_f)(\Omega^2 - \Omega_n^2) \hat{u}^{m,k}_n (r') = -\frac{F_x}{\rho c_{p,n}} \delta(r' - r'_f).
\]

(23)

Using the orthogonality of \( \hat{u}^{m,k}_n (r') \) we obtain after projecting (23) on \( \hat{u}^{m,k}_n (r') \) and integrating over \( V \)

\[
\delta_n^{m,k}(r'_f) = -\frac{\alpha F_x}{c_p \rho (\Omega^2 - \Omega_n^2)} \left( \frac{1}{\| \hat{u}^{m,k}_n (r') \|_V} \right).
\]

(24)

Denoting \( \| \hat{u}^{m,k}_n \| = \left( \int \| \hat{u}^{m,k}_n (r') \|^2 dr' \right)^{1/2} \) the norm of \( \hat{u}^{m,k}_n (r') \) in the space of square integrable functions, we infer that equation (22) is written as

\[
\hat{u}(r') = -\frac{\alpha F_x}{c_p \rho} \sum_{n,m,k} \delta_n^{m,k}(r'_f) \hat{u}^{m,k}_n (r').
\]

(25)

We are now in position to determine \( u(r', t) \) by taking the inverse Fourier transform of (25).

Consequently
\[ u(r', t) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \tilde{u}(r', \omega)e^{-i\omega t} d\omega = \]

\[ = -\frac{1}{2\pi} F_o \sum_{n,m,k} \tilde{u}_n^{m,k}(r'_f) \mathcal{U}_n^{m,k}(r') \frac{1}{\|\mathbf{u}_n^{m,k}\|^2} \int_{-\infty}^{+\infty} e^{-i\omega t} \frac{e^{-i\omega t}}{\omega^2 - \omega_n^2} d\omega \]

where \( \omega_n^k = \frac{c_F n_k}{\alpha} \).

Using complex analysis integration arguments, we finally obtain

\[ u(r', t) = -\frac{i}{2} F_o \sum_{n,m,k} \tilde{u}_n^{m,k}(r'_f) \mathcal{U}_n^{m,k}(r') \frac{e^{i\omega_n^k t}}{\|\mathbf{u}_n^{m,k}\|^2 \omega_n^k}. \]

The explicit forms of \( \tilde{u}_n^{m,k}(r') \) in equation (27) are cited in the previous works [11-18], which refer to the determination of the dynamic characteristics of the corresponding systems.

As a matter of fact

\[ \tilde{u}_n^{m,k}(r') = \tilde{u}_n^{m,k}(r') \text{ for } r' \in V_i \]

with

\[ \tilde{u}_n^{m,k}(r') = \sum_{i=1}^{2} \left\{ \alpha_{m,i}^{n,i} L_{n,i}^{m,i}(r') + \beta_{m,i}^{n,i} M_{n,i}^{m,i}(r') + \gamma_{m,i}^{n,i} N_{n,i}^{m,i}(r') \right\} \bigg|_{\omega = \omega_n^k}, \]

for \( V_i \) elastic, or

\[ \tilde{u}_n^{m,k}(r') = \frac{i}{c_{m,i}} \sum_{i=1}^{2} \alpha_{m,i}^{n,i} L_{n,i}^{m,i}(r') \bigg|_{\omega = \omega_n^k}, \]

for \( V_i \) filled with fluid.
In equations (29) and (30) the summation over \( l \) degenerates to only one term when the origin 0 belongs to \( V_f \) since in this case the spherical Bessel functions of second order must disappear [12].

We note that \( L, M, N \) stand for the Navier eigenvectors given by the relations

\[
L_{n,i}^{l,i}(r') = g_n^l(k_{p,i}^r r') P_n^m(\hat{r}) + \sqrt{n(n+1)} \frac{g_n^l(k_{p,i}^r r')}{k_{p,i}^r} B_n^m(\hat{r})
\]

\[
M_{n,i}^{l,i}(\hat{r}) = \sqrt{n(n+1)} g_n^l(k_{s,i}^r) C_n^m(\hat{r})
\]

\[
N_{n,i}^{l,i}(r') = n(n+1) \frac{g_n^l(k_{s,i}^r r')}{k_{s,i}^r} P_n^m(\hat{r}) + \sqrt{n(n+1)} \left( \frac{g_n^l(k_{s,i}^r r')}{k_{s,i}^r} + \frac{g_n^l(k_{s,i}^r r')}{k_{s,i}^r} \right) B_n^m(\hat{r})
\]

where \( g_n^l(z) \) stands for the derivative of the spherical Bessel \( g_n^l(z) \) \( j_n(z) \) for \( l = 1 \) and \( y_n(z) \) for \( l = 2 \) with respect to its argument and the functions \( P_n^m(\hat{r}), B_n^m(\hat{r}), C_n^m(\hat{r}) \) constitute the vector spherical harmonics given by

\[
P_n^m(\hat{r}) = \hat{r} Y_n^m(\hat{r})
\]

\[
B_n^m(\hat{r}) = \frac{1}{\sqrt{n(n+1)}} \left( \hat{\vartheta} \frac{\partial}{\partial \vartheta} + \hat{\phi} \frac{\partial}{\partial \phi} - \frac{1}{\sin \vartheta} \frac{\partial}{\partial \vartheta} \right) Y_n^m(\hat{r})
\]

\[
C_n^m(\hat{r}) = \frac{1}{\sqrt{n(n+1)}} \left( \hat{\vartheta} \frac{1}{\sin \vartheta} \frac{\partial}{\partial \vartheta} - \hat{\phi} \frac{\partial}{\partial \phi} \right) Y_n^m(\hat{r})
\]

where \( \hat{r}, \hat{\vartheta}, \hat{\phi} \) are the unit vectors in the \( r, \vartheta, \phi \) directions respectively and \( Y_n^m(\hat{r}) \) the spherical harmonics. Finally \( k' \) stands for the dimensionless wave numbers, i.e.,

\[
k_{p,i}^r = \frac{\Omega}{c_{p,i}}, \quad k_{s,i}^r = \frac{\Omega}{c_{s,i}^r}
\]

The coefficients \( \alpha, \beta, \gamma, \delta \) are determined modulo a multiplicative constant - as coefficients of eigenvectors - but this does not alter the expression (27) because as easily can be proved the homogeneous way \( \hat{u}_n^{m,k} \) enters (27) cancels this multiplicative constant.

What remains to be calculated is the norm \( \| \hat{u}_n^{m,k} \| \) appearing in (27).
Clearly,
\[ \left\| \hat{u}_{n,i}^{\alpha,k} \right\|^2 = \sum_{j=0}^{j} \left( \hat{u}_{n,i}^{\alpha,k} (r') \cdot \hat{u}_{n,i}^{\alpha,k} (r') \right) dr' = \sum_{j=0}^{j} \int_{V_i} \hat{u}_{n,i}^{\alpha,k} (r') \cdot \hat{u}_{n,i}^{\alpha,k} (r') dr'. \] (32)

We have then to determine every particular term \( \int_{V_i} \hat{u}_{n,i}^{\alpha,k} (r') \cdot \hat{u}_{n,i}^{\alpha,k} (r') dr' \).

**First Case: \( V_i \) - elastic region**

Inserting expression (29) in the integral and using orthogonality arguments for the Navier eigenvectors, we find that

\[ \int_{V_i} \hat{u}_{n,i}^{\alpha,k} (r') \cdot \hat{u}_{n,i}^{\alpha,k} (r') dr' = \sum_{j=1}^{j} \left[ \frac{\alpha_{n,i}^{\alpha,k}}{\|L_{n,i}^{\alpha,k}(r')\|^2} \right] + \frac{\beta_{n,i}^{\alpha,k}}{\|M_{n,i}^{\alpha,k}(r')\|^2} + \frac{\gamma_{n,i}^{\alpha,k}}{\|N_{n,i}^{\alpha,k}(r')\|^2} \] (33)

where \( \|L_{n,i}^{\alpha,k}(r')\|, \|M_{n,i}^{\alpha,k}(r')\|, \|N_{n,i}^{\alpha,k}(r')\| \) stand for the \( L^2 \) - norms of the corresponding functions in space \( V_i \). Expression (33) is obtained after determining the above mentioned norms and the last integral expressing the inner product of \( L_{n,i}^{\alpha,k} \) and \( N_{n,i}^{\alpha,k} \).

The explicit form of the Navier eigenvectors given in equation (31) indicate that the determination of these norms is a rather difficult task. As a matter of fact, the polar and azimuthal integrations are handled in a straightforward manner, by exploiting orthogonality of spherical harmonic functions. In contrast, the radial integrals have complicated form and was needed tedious and elaborate techniques based on properties of spherical Bessel functions in order to avoid numerical integration and to express all the results in a closed analytical form. We considered this effort necessary in order not to aggravate the problem with numerical error which is controlled with difficulty when someone has to deal with spherical Bessel functions of second order. The expressions for the above quantities are given in Appendix A.

**Second Case: \( V_i \) - fluid region**

In this case, equation (30) leads immediately to the result
\[ \int_{\Omega_i} \hat{a}_{n,i}^{m,k}(r') \cdot \hat{a}_{m,i}^{n,k}(r') \, dr' = \frac{1}{c_i^2} |c_{n,m}^i| \left\| F_{n,i}^L \right\|_{\Omega_0} \]  

and clearly suffices only knowledge of the norm \( \left\| F_{n,i}^L \right\| \) to determine the investigated integral.

3. NUMERICAL RESULTS

For each model the following algorithm is followed:

1. Solve the corresponding homogeneous problem and find \( \Omega_n^k \) and the corresponding vector of coefficients \( x \) from the frequency equation shown in Appendix C for each model.
2. Use a quicksort [19] algorithm to order \( \Omega_n^k \) in ascending order.
3. Use equation (27) to compute the displacement fields under the state of an external Dirac force \( F_0 \).

The frequency equation for each model is solved numerically using a bisection method for \( \Omega_n^k, \, n = 1, 2, 3, \ldots; \, k = 1, 2, 3, \ldots \). A singular value decomposition is used for the determination of each corresponding eigenvector. Those eigenfrequencies are ordered in ascending order using a quicksort algorithm. Equation (27) is used for the computation of the displacement field. An iterative procedure is followed and the number \( k' \) of the eigenfrequencies (and eigenvectors) used and this procedure terminates when \( \left\| u(r', t)^{(k')} - u(r', t)^{(k+1)} \right\| = O\left(10^{-8}\right) \). An example of the numerical results obtained for the FF-Model is shown in Fig. 1 for \( k' = 21, 41, 51 \) for \( u_0 \). It is noted that in our computation the accuracy of the bisection method used is of the order of \( O\left(10^{-8}\right) \) and that the value of \( k' \) for convergence is strongly dependent on the model under discussion.

In what follows we present numerical results for the models considered under the influence of the external stimulus

\[ F_0 = (F_{0x}, F_{0y}, F_{0z}) = (1, 0, 0) \]

applied on
\[ r_f = (r_{f_x}, r_{f_y}, r_{f_\theta}) = (1.0, 0, 0). \]

*Dry Skull (S - Model)*

The material properties used are analogous to those of Ref. 21:

\[
E = 1.379 \times 10^9 \text{ N/m}^2, \quad \nu = 0.25, \quad \rho = 2.132 \times 10^3 \text{ kg/m}^3
\]

\[ r_1 = 0.082m, \quad r_0 = 0.076m \]

The frequency equation matrix is given in Appendix C.1 and its size is 6 X 6 [11]. The value of \( k' \) used in our computations is 35 and we have computed 45 eigenfrequencies for \( 0 \leq n \leq 20 \) and \( 0.0 \leq \Omega_n^k \leq 10.0 \). The results obtained for the displacement fields are shown in Figs. 3 and 4 as a function of time for \( \theta = 0 \) and \( \theta = \pi/2 \), respectively. The time scale displayed corresponds to \( 0 \leq t \leq 1000 \mu \text{sec} \), and in the enclosed framed figure this is extended up to 500 \( \mu \text{sec} \). The corresponding displacement fields as function of \( 0 \leq \phi \leq 2\pi \) for discrete time steps are shown in Fig. 5.

*Two Elastic Spheres (EE - Model)*

The material properties used are similar to those used in Ref. 12:

\[
E_1 = 6.5 \times 10^9 \text{ N/m}^2, \quad \nu_1 = 0.25, \quad \rho_1 = 2.132 \times 10^3 \text{ kg/m}^3
\]

\[
E_0 = \ldots \ldots \text{N/m}^2, \quad \nu_0 = 0.48, \quad \rho_0 = 1.0002 \times 10^3 \text{ kg/m}^3
\]

\[ r_1 = 0.082m, \quad r_0 = 0.076m \]

The frequency equation matrix is given in Appendix C.2 and its size is 9 X 9 [12]. The value of \( k' \) used in our computations is 85 and we have computed 660 eigenfrequencies for \( 0 \leq n \leq 25 \) and \( 0.0 \leq \Omega_n^k \leq 10.0 \). The results obtained for the displacement fields are shown in Figs. 6 and 7 as a function of time for \( \theta = 0 \) and \( \theta = \pi/2 \), respectively. The time scale displayed corresponds to \( 0 \leq t \leq 1000 \mu \text{sec} \) and in the enclosed framed figure this is extended up to 500 \( \mu \text{sec} \). The corresponding displacement fields as function of \( 0 \leq \phi \leq 2\pi \) for discrete time steps are shown in Fig. 8.
Elastic Skull Filled with Fluid (FF - Model)

The material properties used are similar to those used in Ref. 12:

\[ E_i = 6.5 \times 10^9 \text{N/m}^2, \quad \nu_1 = 0.25, \quad \rho_i = 2.132 \times 10^3 \text{kg/m}^3 \]

\[ K = 2.1029753 \times 10^9 \text{N/m}^2, \quad \rho_f = 1.0002 \times 10^3 \text{kg/m}^3 \]

\[ \eta = 0.082 \text{m}, \quad \eta_0 = 0.076 \text{m} \]

The frequency equation matrix is given in Appendix C.3 and its size is 7 X 7 [12]. The value of \( k' \) used in our computations is 51 and we have computed 88 eigenfrequencies for \( 0 \leq n \leq 25 \) and \( 0.0 \leq \Omega_n^k \leq 10.0 \). The results obtained for the displacement fields are shown in Figs. 9 and 10 as a function of time for \( \theta = 0 \) and \( \theta = \pi/2 \), respectively. The time scale displayed corresponds to \( 0 \leq t \leq 100 \mu \text{sec} \) and in the enclosed framed figure this is extended up to 500 \( \mu \text{sec} \). The corresponding displacement fields as function of \( 0 \leq \varphi \leq 2\pi \) for discrete time steps are shown in Fig. 11.

The determination of pressure distribution in the fluid requires special treatment as it is shown below.

From equation (15) follows that

\[ \nabla \cdot \mathbf{u}^{(i)}(r') = \frac{i}{\Omega} \nabla^2 \Phi^{(i)}(r'), \text{ for } r' \neq r_f \]  \hspace{1cm} (35)

and combining equations (13), (14) and (35) we obtain

\[ \hat{p}^{(i)} = -i \Omega \rho', \frac{1}{c_{s,n}^2 \Omega^2} \nabla^2 \Phi^{(i)} = - \rho' \frac{1}{c_{s,n}^2} c_i^2 (\nabla \cdot \mathbf{u}^{(i)}) \]  \hspace{1cm} (36)

However according to (25)

\[ \nabla \cdot \mathbf{u}^{(i)}(r') = \frac{\alpha}{c_{p,n}^2} \sum_{n,m,k} \left( \frac{F_0 \cdot \mathbf{u}^{m,k}_n(r_f)}{(\Omega^2 - \Omega_n^k)^2} \right) \frac{\nabla \cdot \mathbf{u}^{m,k}_n(r_f)}{\mathbf{u}^{m,k}_n} \]  \hspace{1cm} (37)

Given that the \( f \) region is a fluid
\[ \hat{u}^{m,k}_{s,j}(r') = \sum_{i=1}^{c_i} \sum_{n,m,k} c_{s,i}^{n,m,k} L_{s,j}^{n,m,k}(r') \]  

where \( \Psi_{s,j}^{m,l} = g^l_{n}(k'_{p,i} r') Y_n^m(\tilde{r}) \).

Combining (38) with (37) we obtain

\[ \nabla \cdot \hat{u}^{(1)}(r') = \sum_{i=1}^{c_i} \sum_{p,n} \frac{F_0 \cdot \hat{u}^{m,k}_{n}(r')}{\Omega^2 - \Omega^2_{n}} \left[ \sum_{l=1}^{\frac{2}{\Omega^2_{n}}} \left( k'_{p,i} \right) \right] Y_{n}^m(\tilde{r}) \]

or

\[ P^{(1)}(r,t) = -\frac{i\alpha c_i^2}{c_i^2 \sum_{p,n} \sum_{m,k} \frac{F_0 \cdot \hat{u}^{m,k}_{n}(r')}{\Omega^2 - \Omega^2_{n}} \left[ \sum_{l=1}^{\frac{2}{\Omega^2_{n}}} \left( k'_{p,i} \right) \right] Y_{n}^m(\tilde{r}) \]

and taking the inverse transform we finally obtain that

\[ P^{(1)}(r,t) = \frac{\partial c_i^2}{2\alpha c_i^2} \sum_{i,n,m,k} \frac{F_0 \cdot \hat{u}^{m,k}_{n}(r')e^{i\omega_{n}t}}{\omega_{n}^2} \left[ \sum_{l=1}^{2m} \left( \frac{\Omega_{n}^k}{c_i^2} \right) \right] Y_{n}^m(\tilde{r}) \]

The pressure variation is shown in Figs. 12 and 13 as a function of time and space respectively.

4. CONCLUSIONS

We have presented a general approach to the dynamic loading of the human head. The method is based on the solution of the corresponding homogeneous system for its eigenfrequencies and eigenvectors and computation of the displacement fields when a Dirac force in space and time is applied on it. The methodology has been developed for the spherical geometry and the various components of the human head are represented as spherical layers. The exterior layer stands for the skull and the other ones for brain and cerebrospinal fluid. We have used three models to investigate the response of the human head and those include the simple human skull, the fluid filled human skull and the elastic filled human skull. The method can easily be extended to other geometries and to other material properties. The displacement fields presented in this work can be used for the observation of the human head response in various conditions which
involve external cause, such as car accidents or blows in boxing. This can also be used for the computation of intracranial pressure and its variations to estimate sudden increase which becomes very critical and sometimes cause of death.

Acknowledgment
The present work forms part of the project “New Systems for Early Medical Diagnosis and Biotechnological Applications” which is supported by the Greek General Secretariat for Research and Technology through the EU funded R & D Program EPET II.
