Online Social Networks and Media

Mining Content
Content
Goal

How data from micro-blogging (Twitter) is correlated to time series from the financial domain (prices and traded volume)

Which features from tweets are more correlated with changes in the stocks?
Stock Market Data

Stock data from Yahoo! Finance for 150 (randomly selected) companies in the S&P 500 index for the first half of 2010.

For each stock, the daily closing price and daily traded volume

- Transform the price series into its daily relative change, i.e., if the series for price is \( p_i \), we used \( p_i - \frac{p_{i-1}}{p_{i-1}} \).

- Normalized traded volume by dividing the volume of each day by the mean traded volume observed for that company during the entire half of the year.
Twitter Data

Obtain all the relevant tweets on the first half of 2010

- Use a series of regular expressions
  For example, the filter expression for Yahoo is: “#YHOO | $YHOO | #Yahoo”.

- Manual Refinement
  Randomly select 30 tweets from each company, and re-wrote the extraction rules for those sets that had less than 50% of tweets related to the company.

If a rule-based approach not feasible, the company was removed from the dataset

Example companies with expressions rewritten: YHOO, AAPL, APOL
✓ YHOO used in many tweets related with the news service (Yahoo! News).
✓ Apple is a common noun and also used for spamming (“Win a free iPad” scams).
✓ Apollo also the name of a deity in Greek mythology
Graph Representation

### Nodes

- **Tweet**
  - (TweetId, Text, Company, Time)
  - A microblog posting
- **User**
  - (UserId, Name, #Followers, #Friends, Location, Time)
  - A user that posts a tweet or is mentioned
- **Url**
  - (Url, ExpandedUrl, Time)
  - A URL included in a tweet
- **Hashtag**
  - (Hashtag, Time)
  - An annotation used in one tweet

### Edges

- **Annotated**
  - (TweetId, Hashtag, Timestamp)
  - Relate a tweet with one hashtag
- **Re-tweeted**
  - (RTId, TweetId, Time)
  - Represents the re-tweet action
- **Mentioned**
  - (TweetId, UserId, Time)
  - A explicit mention of another user
- **Cited**
  - (TweetId, Url, Time)
  - Connects a URL with tweets including it
- **Created**
  - (TweetId, UserId, Time)
  - Connects a tweet with its author
Constrained Subgraph

$G^c_{t1,t2}$ about company $c$ at time interval $[t1, t2]$

induced subgraph of $G$ that contains the nodes that are either tweets with timestamps in interval $[t1,t2]$, or non-tweet nodes connected through an edge to the selected tweet nodes.

Figure 1: Example of a constrained subgraph for one day and one stock (YHOO). Tweets are presented with red color (+), users are presented with green (@), and URLs with blue (*). Light gray are the similarity nodes (∧)
Features

- **Activity features** count the number of nodes of a particular type, such as number of tweets, number of users, number of hashtags, etc.

- **Graph features** measure properties of the link structure of the graph.

For scalability, feature computation done using Map-Reduce
## Features

<table>
<thead>
<tr>
<th>Activity features</th>

</tr>
<tr>
<td>DEGREE</td>
<td>statistics on the node degree distribution for $G_{t_1,t_2}^c$ (same as above)</td>
</tr>
</tbody>
</table>
Features normalization and seasonability

Most values normalized in [0, 1]

The number of tweets is increasing and has a **weekly seasonal effect**.

Normalize the feature values *with a time-dependent normalization factor* that considers seasonality, i.e., is proportional to the total number of messages on each day.
Time Series Correlation

Cross-correlation coefficient (CCF) at lag $\tau$ between series $X$, $Y$ measures the correlation of the first series with respect to the second series shifted by $\tau$

$$R(\tau) = \frac{\sum_i ((X(i) - \mu_X)(Y(i-\tau) - \mu_Y))}{\sqrt{\sum_i (X(i) - \mu_X)^2} \sqrt{\sum_i (Y(i-\tau) - \mu_Y)^2}}$$

If correlation at a negative lag, then input features can be used to predict the outcome series
## Results

Results

Index graph with data related to the 20 biggest companies (appropriately weighted)

Centrality measures (PageRank, Degree) work better
Expanding the graph

Restricted Graph

Expanded Graph: all tweets that contain $ticker or #ticker, the full name of the company, short name version after removing common suffixes (e.g., inc or corp), or short name as a hash-tag. Example: “#YHOO | $YHOO | #Yahoo | Yahoo | Yahoo Inc”.

RestExp: Add to the restricted graph the tweets of the expanded graph that are reachable from the nodes of the restricted graph through a path (e.g., through a common author or a re-tweet).
Simulation

Goal: simulate daily trading to see if using twitter helps

Description of the Simulator
An investor
1. starts with an initial capital endowment $C_0$.
2. in the morning of every day $t$, buys $K$ different stocks using all of the available capital $C_t$ using a number of stock selection strategies
3. holds the stocks all day
4. sells all the stocks at the closing time of day $t$. The amount obtained is the new capital $C_{t+1}$ used again in step 2.

This process finishes on the last day of the simulation.

Plot the percent of money win or lost each day against the original investment.
Stock selection strategies

Random: buys K stocks at *random*, spends Ct/K per stock (uniformly shared).

Fixed: buys K stocks using a *particular financial indicator* (market capitalization, company size, total debt), from the same companies every day, spends Ct/K per stock (uniformly shared).

Auto Regression: buys the K stocks whose *price changes* will be larger, predicted using an auto-regression (AR(s)) model.

\[
x_t = a_1 x_{t-1} + a_2 x_{t-1} \ldots a_m x_{t-m} + c
\]

spends Ct/K per stock (uniformly shared) or use a price-weight ratio

\[
weight = \frac{\text{price difference}}{\text{open price}}
\]
Stock selection strategies

Twitter-Augmented Regression: buys the best K stocks that are predicted using a vector auto-regressive (VAR(s)) model that considers, in addition to price, a Twitter feature

\[ x_t = a_1 x_{t-1} + a_2 x_{t-2} \ldots a_m x_{t-m} + b_1 y_{t-1} + b_2 y_{t-2} \ldots b_m y_{t-m} + c. \]

spends Ct/K per stock (uniformly shared) or use a price-weight ratio
average loss for Random is -5.52%, for AR -8.9% (Uniform) and -13.08% (Weighted), for Profit Margin - 3.8%, Best use NUN-CMP on RestExp with uniform share + 0.32% (on restricted graph -2.4% loss )

Includes tDow Jones Index he Average (DJA) (consistent)
Summary

- Present filtering methods to create graphs of postings about a company during a time interval and a suite of features that can be computed from these graphs.

- Study the correlation of the proposed features with the time series of stock price and traded volume also show how these correlations can be stronger or weaker depending on financial indicators of companies (e.g., on current level of debt).

- Perform a study on the application of the correlation patterns found to guide a stock trading strategy and show that it can lead to a strategy that is competitive when compared to other automatic trading strategies.
Takeshi Sakaki, Makoto Okazaki, Yutaka Matsuo: *Earthquake shakes Twitter users: real-time event detection by social sensors.* WWW 2010: 851-860
Goal

- investigate the real-time interaction of events such as earthquakes, in Twitter, and

- propose an algorithm to monitor tweets and to detect a target event.
Twitter and Earthquakes in Japan

The intersection is regions with many earthquakes and large Twitter users.
Twitter and Earthquakes in Japan

Other regions:
Indonesia, Turkey, Iran, Italy, and Pacific coastal US cities
What is an event?

*an arbitrary* classification of a space/time region.

**Example social events:** large parties, sports events, exhibitions, accidents, political campaigns.

**Example natural events:** storms, heavy rainfall, tornadoes, typhoons/hurricanes/cyclones, earthquakes.

**Several properties:**

I. large scale (many users experience the event),
II. influence daily life (for that reason, many tweets)
III. have spatial and temporal regions (so that real-time location estimation would be possible).
Event detection algorithms

- do *semantic analysis* on tweets
  - to obtain tweets on the target event precisely

- regard Twitter user as a *sensor*
  - to *detect* the target event
  - to *estimate location* of the target
Semantic Analysis on Tweets

- Search tweets including keywords related to a target event – *query keywords*
  - Example: In the case of earthquakes
    - “shaking”, “earthquake”

- Classify tweets into a positive class (*real time reports of the event*) or a negative class
  - Example:
    - “Earthquake right now!!” ---positive
    - “Someone is shaking hands with my boss” --- negative
    - “Three earthquakes in four days. Japan scares me” --- negative

- Build a *classifier*
Semantic Analysis on Tweets

- Create classifier for tweets
  - use Support Vector Machine (SVM)

- Features (Example: I am in Japan, earthquake right now!)
  - Statistical features (A) (7 words, the 5th word)
    - the number of words in a tweet message and the position of the query within a tweet
  - Keyword features (B) (I, am, in, Japan, earthquake, right, now)
    - the words in a tweet
  - Word context features (C) (Japan, right)
    - the words before and after the query word
Tweet as a Sensory Value

Event detection from twitter

Object detection in ubiquitous environment

the correspondence between tweets processing and sensory data detection
Tweet as a Sensory Value

We can apply methods for sensory data detection to tweets processing.

Some users posts “earthquake right now!!”

- Detect an earthquake
- Search and classify them into positive class
- Detection from Twitter
- Object detection in ubiquitous environment
- Some earthquake sensors responses positive value

Probabilistic model
Classifier
Probabilistic model
Target event
Target object
Earthquake occurrence
Observation by Twitter users
Observation by sensors
Values

Event detection from twitter
Object detection in ubiquitous environment
Tweet as a Sensory Value

- We make two assumptions to apply methods for observation by sensors

  - **Assumption 1:** Each Twitter user is regarded as a sensor
    - a tweet → a sensor reading
    - a sensor detects a target event and makes a report probabilistically
    - Example:
      - make a tweet about an earthquake occurrence
      - “earthquake sensor” return a positive value

  - **Assumption 2:** Each tweet is associated with a time and location
    - a time : post time
    - location : GPS data or location information in user’s profile

Processing time information and location information, we can detect target events and estimate location of target events
Probabilistic Model

- Why a probabilistic model?
  - Sensor values (tweets) are noisy and sometimes sensors work incorrectly
  - We cannot judge whether a target event occurred or not from one tweet
  - We have to calculate the probability of an event occurrence from a series of data

- We propose probabilistic models for
  - detecting events from time-series data
  - estimating the location of an event from sensor readings
Temporal Model

• We must calculate the probability of an event occurrence from multiple sensor values

• We examine the actual time-series data to create a temporal model
Temporal Model

$y = e^{-\frac{x}{\tau}}$
Temporal Model

- the data fits very well to an exponential function with probability density function

\[ f(t; \lambda) = \lambda e^{-\lambda t} \quad (t > 0, \lambda > 0) \quad \lambda = 0.34 \]

- Inter-arrival time (time between events) of a Poisson process, i.e., a process in which events occur continuously and independently at a constant average rate
  - If a user detects an event at time 0, the probability of a tweet from \( t \) to \( \Delta t \) is fixed (\( \lambda \))
Temporal Model

- Combine data from many sensors (tweets) based on two assumptions
  - false-positive ratio \( p_f \) of a sensor (approximately 0.35)
  - sensors are assumed to be independent and identically distributed (i.i.d.)

The probability of an event occurrence at time \( t \)

\[
p_{\text{occur}}(t) = 1 - p_f^{n(t)}
\]

\( n(t) \) total number of sensors (tweets) expected at time \( t \)
Temporal Model

• the probability of an event occurrence at time t
  \[ P_{\text{occur}}(t) = 1 - p_f^n_0 \left( \frac{1-e^{-\lambda(t+1)}}{1-e^{-\lambda}} \right) \]
  – sensors at time 0 \rightarrow n_0 \text{ sensors at time } t \quad n_0 e^{-\lambda t}
  – the number of sensors at time t \quad n_0 \left( 1 - e^{-\lambda(t+1)} \right) / \left( 1 - e^{-\lambda} \right)

• expected wait time \( t_{\text{wait}} \) to deliver notification to achieve false positive 1% have to wait for
  \[ t_{\text{wait}} = \left( 1 - \left( 0.1264/n_0 \right) \right) / 0.7117 - 1 \]
  – parameter
  \[ \lambda = 0.34, \quad p_f = 0.35, \quad p_{\text{occur}} = 0.99 \]
Location Estimation

• Compute the target location given a sequence of locations and an i.i.d process noise sequence

• Estimate target recursively
Bayesian Filters for Location Estimation

• Kalman Filters
  – are the most widely used variant of Bayes filters
  – Assume that the posterior density at every time is Gaussian, parameterized by a mean and covariance
  – For earthquakes: (longitude, latitude) for typhoons also velocity
  – advantages: computational efficiency
  – disadvantages: being limited to accurate sensors or sensors with high update rates
Particle Filters

- Particle Filters
  - represent the probability distribution by sets of samples, or particles
  - advantages: the ability to represent arbitrary probability densities
    - particle filters can converge to the true posterior even in non-Gaussian, nonlinear dynamic systems.
  - disadvantages: the difficulty in applying to high-dimensional estimation problems
Step 1: Sample tweets associated with locations and get user distribution proportional to the number of tweets in each region

---

**Algorithm 1 Particle filter algorithm**

1. **Initialization:** Calculate the weight distribution $D_w(x, y)$ from twitter users geographic distribution in Japan.
2. **Generation:** Generate and weight a particle set, which means $N$ discrete hypothesis. 
   (1) Generate a particle set $S_0 = (s_0,0, s_0,1, s_0,2, \ldots, s_0, N-1)$ and allocate them on the map evenly: particle $s_{0,k} = (x_{0,k}, y_{0,k}, \text{weight}_{0,k})$, where $x$ corresponds to the longitude and $y$ corresponds to the latitude.
   (2) Weight them based on weight distribution $D_w(x, y)$.
3. **Re-sampling**
   (1) Re-sample $N$ particles from a particle set $S_t$ using weights of each particles and allocate them on the map. (We allow to re-sample same particles more than one.)
   (2) Generate a new particle set $S_{t+1}$ and weight them based on weight distribution $D_w(x, y)$.
4. **Prediction:** Predict the next state of a particle set $S_t$ from the Newton’s motion equation.

\[
\begin{align*}
(x_{t,k}, y_{t,k}) &= (x_{t-1,k} + v_{x,t-1} \Delta t + \frac{a_{x,t-1} \Delta t^2}{2}, \\
y_{t-1,k} + v_{y,t-1} \Delta t + \frac{a_{y,t-1} \Delta t^2}{2}) \\
(v_{x,t}, v_{y,t}) &= (v_{x,t-1} + a_{x,t-1}, v_{y,t-1}, a_{y,t-1})
\end{align*}
\]

$a_{x,t} = \mathcal{N}(0; \sigma^2)$, $a_{y,t} = \mathcal{N}(0; \sigma^2)$.
5. **Weighing:** Re-calculate the weight of $S_t$ by measurement $m(m_x, m_y)$ as follows.

\[
\begin{align*}
dx_k &= m_x - x_{t,k}, \\
dy_k &= m_y - y_{t,k} \\
w_{t,k} &= D_w(x_{t,k}, y_{t,k}) \cdot \frac{1}{(\sqrt{2\pi}\sigma)} \cdot \exp \left(-\frac{(dx_k^2 + dy_k^2)}{2\sigma^2}\right)
\end{align*}
\]
6. **Measurement:** Calculate the current object location $o(x_t, y_t)$ by the average of $s(x_t, y_t) \in S_t$.
7. **Iteration:** Iterate Step 3, 4, 5 and 6 until convergence.
Information Diffusion

• Proposed spatiotemporal models need to meet one condition that
  – Sensors are assumed to be independent

• We check if information diffusion about target events happens because
  – if an information diffusion happened among users, Twitter user sensors are not independent. They affect each other
In the case of an earthquakes and a typhoons, very little information diffusion takes place on Twitter, compared to Nintendo DS Game. → We assume that Twitter user sensors are independent about earthquakes and typhoons.
Algorithm: Event detection and location estimation algorithm.

1. Given a set of queries $Q$ for a target event.
2. Put a query $Q$ using search API every $s$ seconds and obtain tweets $T$.
3. For each tweet $t \in T$, obtain features $A$, $B$, and $C$. Apply the classification to obtain value $v_t = \{0, 1\}$.
4. Calculate event occurrence probability $p_{\text{occur}}$ using $v_t$, $t \in T$; if it is above the threshold $p^{\text{thre}}_{\text{occur}}$, then proceed to step 5.
5. For each tweet $t \in T$, we obtain the latitude and the longitude $l_t$ by i) utilizing the associated GPS location, ii) making a query to Google Map the registered location for user $u_t$. Set $l_t = \text{null}$ if both do not work.
6. Calculate the estimated location of the event from $l_t$, $t \in T$ using Kalman filtering or particle filtering.
7. (optionally) Send alert e-mails to registered users.
Evaluation of Semantic Analysis

- **Queries**
  - Earthquake query: “shaking” and “earthquake”
  - Typhoon query: “typhoon”

- **Examples to create classifier**
  - 597 positive examples

Discussions of Experiments

- Particle filters performs better than other methods.
- If the center of a target event is in the sea, it is more difficult to locate it precisely from tweets.
- It becomes more difficult to make good estimation in less populated areas.
Earthquake Reporting System

• Toretter (http://toretter.com)
  – Earthquake reporting system using the event detection algorithm
  – All users can see the detection of past earthquakes
  – Registered users can receive e-mails of earthquake detection reports

Dear Alice,

We have just detected an earthquake around Chiba. Please take care.

- Lots of earthquakes
- Earthquake
- It shook
- Terrible earthquake
- Earthquake!!
- Earthquake! My gosh!
- Oh, earthquake?
- I feel earthquake!
- Shook Aichi
- Earthquake again. This is a long one...
- Earthquake now.
Earthquake Reporting System

• Effectiveness of alerts of this system
  – Alert E-mails urges users to prepare for the earthquake if they are received by a user shortly before the earthquake actually arrives.

• Is it possible to receive the e-mail before the earthquake actually arrives?
  – An earthquake is transmitted through the earth's crust at about 3~7 km/s.
  – A person has about 20~30 sec before its arrival at a point that is 100 km distant from an actual center.
## Results of Earthquake Detection

In all cases, we sent E-mails before announces of JMA. In the earliest cases, we can sent E-mails in 19 sec.

We detected 96% of earthquakes that were stronger than scale 3 or more during the period.
Summary

- We investigated the real-time nature of Twitter for event detection
- Semantic analysis were applied to tweets classification
- We consider each Twitter user as a sensor and set a problem to detect an event based on sensory observations
- Location estimation methods such as Kaman filters and particle filters are used to estimate locations of events

- We developed an earthquake reporting system, which is a novel approach to notify people promptly of an earthquake event
- We plan to expand our system to detect events of various kinds such as rainbows, traffic jam etc.

Some slides are from Jure Leskovec’s course “On Social Information Network Analysis”
Goal

Track units of information as the evolve over time

How? Extract textual fragments that travel relatively unchanged, through many articles:

*Look for phrases inside quotes:* “...” About 1.25 quotes per document in our data

Why it works?
Quotes are
- integral parts of journalistic practices
- tend to follow iterations of a story as it evolves
- are attributed to individuals and have time and location
Approach

**Item**: a news article or blog post

**Phrase**: a quoted string that occurs in one or more items

Produce **phrase clusters**, which are collections of phrases that are close textual variants of one another.

1. *Build a phrase graph* where each phrase is represented by a node and directed edges connect related phrases.

2. *Partition the graph* in such a way that its components are the phrase clusters.
Phrase Graph

A graph $G$ on the set of quoted phrases:

$V = \text{phrases}$

An edge $(p, q)$

- $p$ is strictly shorter than $q$, and
- $p$ has directed edit distance to $q$ less than a small threshold or there is at least a $k$-word consecutive overlap between the phrases

Weights $w(p, q)$: decrease with edit distance from $p$ to $q$, and increase in the frequency of $q$ in the corpus (the inclusion of $p$ in $q$ is supported by many occurrences of $q$)

$G$ is a DAG
Quote: Our opponent is someone who sees America, it seems, as being so imperfect, imperfect enough that he’s palling around with terrorists who would target their own country.”
Phrase Graph Construction

Preprocessing:

- a lower bound $L$ on the word-length of phrases
- a lower bound $M$ on their frequency
- eliminate phrases for which at least an $\varepsilon$ fraction occurs on a single domain (produced by spammers.)
Central idea: look for a collection of phrases that “belong” either to a single long phrase \(q\), or to a single collection of phrases.

The outgoing paths from all phrases in the cluster should flow into a single root node \(q\) (node with no outgoing edges) -> look for a subgraph for which all paths terminate in a single root node.

How?
Delete edges of small total weight from the phrase graph, so it falls apart into disjoint pieces, where each piece “feeds into” a single root phrase that can serve as the exemplar for the phrase cluster.
Phrase Graph

Nodes are phrases

BCD

BDXYC

ABCD

ABCEFG

CEFP

CEF

CEFPQR

UVCEXF
Phrase Graph

Nodes are phrase
Edges are inclusion relations
Phrase Graph

Nodes are phrases
Edges are inclusion relations
Edges have weights
Objective: In a directed acyclic graph (approx. phrase inclusion), delete min total edge weight s.t. each connected component has a single “sink” node.
The DAG Partitioning Problem: Given a directed acyclic graph with edge weights, delete a set of edges of minimum total weight so that each of the resulting components is single-rooted.

DAG Partitioning is NP-hard.
In any optimal solution, there is at least one outgoing edge from each non-root node that has not been deleted.

A subgraph of the DAG where each non-root node has only a single out-edge must necessarily have single-rooted components, since the edge sets of the components will all be in-branching trees.

If for each node we happened to know just a single edge that was not deleted in the optimal solution, then the subgraph consisting of all these edges would have the same components (when viewed as node sets) as the components in the optimal solution of DAG Partitioning.

It is enough to find a single edge out of each node that is included in the optimal solution to identify the optimal components.
Phrase Graph Partitioning Heuristic

Choose for each non-root node a single outgoing edge.

Which one?
When compared to the total amount of edge weight kept in the clusters, if a random edge out of each phrase is kept, an edge to the shortest phrase gives 9% improvement, an edge to the most frequent phrase gives 12%.

Proceed from the roots down the DAG and greedily assign each node to the cluster to which it has the most edges (gives 13% improvement)

simulated annealing did not improve the solution
Data Set

- Since 2008 we have been collecting nearly all blog posts and news articles:
  - 6 billion documents
  - 20 TB of data
- **Solution:** Graph stream clustering
  - Phrases arrive in a stream
  - Simultaneously cluster the graph and attach phrases to the graph
  - Dynamically remove completed clusters
Temporal variation

... is periodic, has no trends.
"Bandwidth" of the online media is constant

Can we extract any interesting temporal variations?
Temporal variation

**Thread** associated with a given phrase cluster: the set of all items (news articles or blog posts) containing some phrase from the cluster

**Track all threads over time**, considering both their individual temporal dynamics as well as their interactions with one another.
Temporal variation

Figure 4: Top 50 threads in the news cycle with highest volume for the period Aug. 1 – Oct. 31, 2008. Each thread consists of all news articles and blog posts containing a textual variant of a particular quoted phrases. (Phrase variants for the two largest threads in each week are shown as labels pointing to the corresponding thread.) The data is drawn as a stacked plot in which the thickness of the strand corresponding to each thread indicates its volume over time. Interactive visualization is available at http://memetracker.org.
Thread volume increase and decay

Peak time of a thread: median time one would expect the overall volume of a thread to be very low initially; then the volume would rise; and slowly decay. But rise and drop in volume surprisingly symmetric around the peak. Two distinct types of behavior:

- the volume outside an 8-hour window centered at the peak modeled by an exponential function
- the 8-hour time window around the peak is best modeled by a logarithmic function

Figure 7: Thread volume increase and decay over time. Notice the symmetry, quicker decay than buildup, and lower baseline popularity after the peak.
Lag between news and blogs

- **Using Google News we label:**
  - Mainstream media: **20,000 sites** (44% vol.)
  - Blog (everything else): **1.6 million sites** (56% vol.)

Peak blog intensity comes about 2.5 hours after news peak.
Lag of individual sites

**Table 2:** Phrases first discovered by blogs and only later adopted by the news media. $M$: total phrase volume, $f_b$: fraction of blog mentions before 1 week of the news media peak.
Conclusions

a framework for tracking short, distinctive phrases

scalable algorithms for identifying and clustering textual variants of such phrases that scale to a collection of 90 million articles

Slides are from Jure Leskovec’s course “On Social Information Network Analysis”
- Tracking Hyperlinks on the Blogosphere

- Identify cascades – graphs induced by a time ordered propagation of hyperlinks
Cascade shapes (ranked by frequency)
Most of cascades are trees:

- Number of edges is smaller than the number of nodes in a cascade
- Diameter increases logarithmically
- **Cascade sizes follow a heavy-tailed distribution**
  - **Viral marketing:**
    - Books: steep drop-off: power-law exponent -5
    - DVDs: larger cascades: exponent -1.5
  - **Blogs:**
    - Power-law exponent -2
  - **What’s a good model?**
    - What role does the underlying social network play?
    - Can make a step towards more realistic cascade generation (propagation) model?
1) Randomly pick blog to infect, add to cascade.

2) Infect each in-linked neighbor with probability $\beta$.

3) Add infected neighbors to cascade.

4) Set node infected in (i) to uninfected.
Generative model produces realistic cascades

$\beta = 0.025$

Most frequent cascades
