Online Social Networks and Media

Link Analysis and Web Search
How to Organize the Web

First try: Human curated Web directories
Yahoo, DMOZ, LookSmart
How to organize the web

• Second try: Web Search
  – Information Retrieval investigates:
    • Find relevant docs in a small and trusted set e.g., Newspaper articles, Patents, etc. ("needle-in-a-haystack")
    • Limitation of keywords (synonyms, polysemy, etc)
  • But: Web is huge, full of untrusted documents, random things, web spam, etc.

  - Everyone can create a web page of high production value
  - Rich diversity of people issuing queries
  - Dynamic and constantly-changing nature of web content
Size of the Search Index

http://www.worldwidewebsize.com/
How to organize the web

• Third try (the Google era): using the web graph
  – Swift from relevance to authoritativeness
  – It is not only important that a page is relevant, but that it is also important on the web

• For example, what kind of results would we like to get for the query “greek newspapers”?
Link Analysis

• Not all web pages are equal on the web
• The links act as endorsements:
  – When page p links to q it endorses the content of the content of q

What is the simplest way to measure importance of a page on the web?
Rank by Popularity

- Rank pages according to the number of incoming edges (in-degree, degree centrality)

1. Red Page
2. Yellow Page
3. Blue Page
4. Purple Page
5. Green Page
• It is not important only how many link to you, but also how important are the people that link to you.

• **Good** authorities are pointed by **good** authorities
  – Recursive definition of importance
THE PAGERANK ALGORITHM
PageRank

• **Good** authorities should be pointed by **good** authorities
  – The value of a node is the value of the nodes that point to it.

• **How do we implement that?**
  – Assume that we have a **unit of authority** to distribute to all nodes.
    • Initially each node gets $\frac{1}{n}$ amount of authority
  – Each node **distributes** the authority value they have to their neighbors
  – The authority value of each node is the sum of the **authority fractions** it collects from its neighbors.

$w_v = \sum_{u \to v} \frac{1}{d_{out}(u)} w_u$

$w_v$: the PageRank value of node $v$

Recursive definition
A simple example

- Solving the system of equations we get the authority values for the nodes
  - $w = \frac{1}{2}$, $w = \frac{1}{4}$, $w = \frac{1}{4}$
A more complex example

\[ w_1 = \frac{1}{3} w_4 + \frac{1}{2} w_5 \]
\[ w_2 = \frac{1}{2} w_1 + w_3 + \frac{1}{3} w_4 \]
\[ w_3 = \frac{1}{2} w_1 + \frac{1}{3} w_4 \]
\[ w_4 = \frac{1}{2} w_5 \]
\[ w_5 = w_2 \]

\[ w_v = \sum_{u \to v} \frac{1}{d_{out}(u)} w_u \]
Computing PageRank weights

- A simple way to compute the weights is by iteratively updating the weights.
- PageRank Algorithm

\[ w_v = \frac{1}{d_{out}(u)} \frac{1}{n} \sum_{u \rightarrow v} w_u \]

- This process converges.
Initially, all nodes PageRank 1/8

- As a kind of “fluid” that circulates through the network
- The total PageRank in the network remains constant (no need to normalize)
A simple way to check whether an assignment of numbers forms an equilibrium set of PageRank values: check that they sum to 1, and check that when apply the Basic PageRank Update Rule, we get the same values back.

If the network is strongly connected then there is a unique set of equilibrium values.
Random Walks on Graphs

• The algorithm defines a random walk on the graph

• Random walk:
  – Start from a node chosen uniformly at random with probability $\frac{1}{n}$.
  – Pick one of the outgoing edges uniformly at random
  – Move to the destination of the edge
  – Repeat.

• The Random Surfer model
  – Users wander on the web, following links.
• Step 0
Example

• Step 0
Example

- Step 1
Example

• Step 1
Example

• Step 2
Example

• Step 2
Example

• Step 3
Example

• Step 3
Example

• Step 4...
Random walk

• Question: what is the probability $p_i^t$ of being at node $i$ after $t$ steps?

\[
\begin{align*}
    p_1^0 &= \frac{1}{5} \\
    p_2^0 &= \frac{1}{5} \\
    p_3^0 &= \frac{1}{5} \\
    p_4^0 &= \frac{1}{5} \\
    p_5^0 &= \frac{1}{5}
\end{align*}
\]

\[
\begin{align*}
    p_1^t &= \frac{1}{3} p_4^{t-1} + \frac{1}{2} p_5^{t-1} \\
    p_2^t &= \frac{1}{2} p_1^{t-1} + p_3^{t-1} + \frac{1}{3} p_4^{t-1} \\
    p_3^t &= \frac{1}{2} p_1^{t-1} + \frac{1}{3} p_4^{t-1} \\
    p_4^t &= \frac{1}{2} p_5^{t-1} \\
    p_5^t &= p_2^{t-1}
\end{align*}
\]
Markov chains

• A Markov chain describes a **discrete time stochastic process** over a set of states
  \[ S = \{s_1, s_2, \ldots, s_n\} \]
  according to a transition probability matrix \( P = \{P_{ij}\} \)
  \[ P_{ij} = \text{probability of moving to state } j \text{ when at state } i \]

• Matrix \( P \) has the property that the entries of all rows sum to 1
  \[ \sum_j P[i,j] = 1 \]
  A matrix with this property is called **stochastic**

• **State probability distribution**: The vector \( p^t = (p_1^t, p_2^t, \ldots, p_n^t) \) that stores the probability of being at state \( s_i \) after \( t \) steps

• **Memorylessness property**: The next state of the chain depends only at the current state and not on the past of the process (first order MC)
  \[ \text{Higher order MCs are also possible} \]

• **Markov Chain Theory**: After infinite steps the state probability vector converges to a unique distribution if the chain is **irreducible and aperiodic**
Random walks

- Random walks on graphs correspond to Markov Chains
  - The set of states $S$ is the set of nodes of the graph $G$
  - The transition probability matrix is the probability that we follow an edge from one node to another
    $$ P[i, j] = 1 / \text{deg}_{out}(i) $$
### An example

**Transition Matrix**

$$A = \begin{bmatrix}
0 & 1 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 \\
1 & 1 & 1 & 0 & 0 \\
1 & 0 & 0 & 1 & 0
\end{bmatrix}$$

**Transition Probability Matrix**

$$P = \begin{bmatrix}
0 & 1/2 & 1/2 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 \\
1/3 & 1/3 & 1/3 & 0 & 0 \\
1/2 & 0 & 0 & 0 & 1/2 & 0
\end{bmatrix}$$

**Graph Representation**

The graph on the right visualizes the transition matrix and probability matrix. Each node represents a state, and the arrows indicate transitions with corresponding probabilities.
Node Probability vector

• The vector $p^t = (p^t_1, p^t_2, ..., p^t_n)$ that stores the probability of being at node $v_i$ at step $t$

• $p^0_i = \text{the probability of starting from state } i \text{ (usually) set to uniform}$

• We can compute the vector $p^t$ at step $t$ using a vector-matrix multiplication

$$p^t = p^{t-1} P$$
An example

\[ P = \begin{bmatrix}
0 & 1/2 & 1/2 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 \\
1/3 & 1/3 & 1/3 & 0 & 0 \\
1/2 & 0 & 0 & 1/2 & 0
\end{bmatrix} \]

\[
p_1^t = \frac{1}{3} p_4^{t-1} + \frac{1}{2} p_5^{t-1}
\]

\[
p_2^t = \frac{1}{2} p_1^{t-1} + p_3^{t-1} + \frac{1}{3} p_4^{t-1}
\]

\[
p_3^t = \frac{1}{2} p_1^{t-1} + \frac{1}{3} p_4^{t-1}
\]

\[
p_4^t = \frac{1}{2} p_5^{t-1}
\]

\[
p_5^t = p_2^{t-1}
\]
Stationary distribution

• The **stationary distribution** of a random walk with transition matrix $P$, is a probability distribution $\pi$, such that $\pi = \pi P$

• The stationary distribution is an **eigenvector** of matrix $P$ — the **principal left eigenvector** of $P$ — stochastic matrices have maximum eigenvalue 1

• The probability $\pi_i$ is the fraction of times that we visited state $i$ as $t \to \infty$

• **Markov Chain Theory**: The random walk converges to a **unique stationary distribution** independent of the initial vector if the graph is **strongly connected**, and **not** bipartite.
Computing the stationary distribution

• The **Power Method**

  Initialize $q^0$ to some distribution
  Repeat
  \[ q^t = q^{t-1}P \]
  Until convergence

• After **many** iterations $q^t \to \pi$ regardless of the initial vector $q^0$

• Power method because it computes $q^t = q^0P^t$

• Rate of convergence
  - determined by the second eigenvalue $\lambda_2^t$
The stationary distribution

• What is the meaning of the stationary distribution $\pi$ of a random walk?
• $\pi(i)$: the probability of being at node $i$ after very large (infinite) number of steps
• $\pi = p_0 P^\infty$, where $P$ is the transition matrix, $p_0$ the original vector
  – $P(i, j)$: probability of going from $i$ to $j$ in one step
  – $P^2(i, j)$: probability of going from $i$ to $j$ in two steps (probability of all paths of length 2)
  – $P^\infty(i, j) = \pi(j)$: probability of going from $i$ to $j$ in infinite steps – starting point does not matter.
The PageRank random walk

• Vanilla random walk
  – make the adjacency matrix stochastic and run a random walk

\[
P = \begin{bmatrix}
0 & 1/2 & 1/2 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 & 0 \\
1/3 & 1/3 & 1/3 & 0 & 0 \\
1/2 & 0 & 0 & 1/2 & 0 \\
\end{bmatrix}
\]
The PageRank random walk

• What about sink nodes?
  – what happens when the random walk moves to a node without any outgoing links?

\[
P = \begin{bmatrix}
0 & 1/2 & 1/2 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
1/3 & 1/3 & 1/3 & 0 & 0 \\
1/2 & 0 & 0 & 1/2 & 0 \\
\end{bmatrix}
\]
The PageRank random walk

- Replace these row vectors with a vector $v$
  - typically, the uniform vector

$$P' = P + dv^T$$

$$d = \begin{cases} 
1 & \text{if } i \text{ is sink} \\
0 & \text{otherwise}
\end{cases}$$
The PageRank random walk

- What about loops?
  - Spider traps
The PageRank random walk

• Add a **random jump** to vector \( \mathbf{v} \) with prob \( 1-\alpha \)
  – typically, to a uniform vector

• Restarts after \( 1/(1-\alpha) \) steps in expectation
  – Guarantees irreducibility, convergence

\[
P'' = \alpha \begin{bmatrix} 0 & 1/2 & 1/2 & 0 & 0 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 0 & 1 & 0 & 0 & 0 \\ 1/3 & 1/3 & 1/3 & 0 & 0 \\ 1/2 & 0 & 0 & 0 & 1/2 \end{bmatrix} + (1-\alpha) \begin{bmatrix} 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \end{bmatrix}
\]

\[
P'' = \alpha \mathbf{P}' + (1-\alpha) \mathbf{u} \mathbf{v}^T, \text{ where } \mathbf{u} \text{ is the vector of all } 1\text{s}
\]

Random walk with restarts
PageRank algorithm [BP98]

- The Random Surfer model
  - pick a page at random
  - with probability $1 - \alpha$ jump to a random page
  - with probability $\alpha$ follow a random outgoing link
- Rank according to the stationary distribution
- \[
  PR(p) = \alpha \sum_{q \rightarrow p} \frac{PR(q)}{|Out(q)|} + (1 - \alpha) \frac{1}{n}
\]

\[\alpha = 0.85 \text{ in most cases}\]
PageRank: Example
Stationary distribution with random jump

- If $\mathbf{v}$ is the jump vector

  $p^0 = \mathbf{v}$

  $p^1 = \alpha p^0 P + (1 - \alpha) \mathbf{v} = \alpha \mathbf{v} P + (1 - \alpha) \mathbf{v}$

  $p^2 = \alpha p^1 P + (1 - \alpha) \mathbf{v} = \alpha^2 \mathbf{v} P^2 + (1 - \alpha) \mathbf{v} \alpha P + (1 - \alpha) \mathbf{v}$

  $\vdots$

  $p^\infty = (1 - \alpha) \mathbf{v} + (1 - \alpha) \mathbf{v} \alpha P + (1 - \alpha) \mathbf{v} \alpha^2 P^2 + \cdots = (1 - \alpha) (I - \alpha P)^{-1}$

- With the random jump the shorter paths are more important, since the weight decreases exponentially
  - makes sense when thought of as a restart

- If $\mathbf{v}$ is not uniform, we can bias the random walk towards the nodes that are close to $\mathbf{v}$
  - Personalized and Topic-Specific Pagerank.
Effects of random jump

- Guarantees convergence to unique distribution
- Motivated by the concept of random surfer
- Offers additional flexibility
  - personalization
  - anti-spam
- Controls the rate of convergence
  - the second eigenvalue of matrix $P''$ is $\alpha$
Random walks on undirected graphs

• For undirected graphs, the stationary distribution is proportional to the degrees of the nodes
  – Thus in this case a random walk is the same as degree popularity

• This is not longer true if we do random jumps
  – Now the short paths play a greater role, and the previous distribution does not hold.
Pagerank implementation

- Store the graph in adjacency list, or list of edges
- Keep current pagerank values and new pagerank values
- Go through edges and update the values of the destination nodes.
- Repeat until the difference ($L_1$ or $L_\infty$ difference) is below some small value $\varepsilon$. 
A (Matlab-friendly) PageRank algorithm

- Performing vanilla power method is now too expensive – the matrix is not sparse

\[
q^0 = v \\
t = 1 \\
\text{repeat} \\
\quad q^t = (P'')^T q^{t-1} \\
\quad \delta = \|q^t - q^{t-1}\| \\
\quad t = t + 1 \\
\text{until } \delta < \varepsilon
\]

Efficient computation of \( y = (P'')^T x \)

\[
y = aP^T x \\
\beta = \|x\|_1 - \|y\|_1 \\
y = y + \beta v
\]

- \( P = \) normalized adjacency matrix
- \( P' = P + dv^T \), where \( d_i \) is 1 if \( i \) is sink and 0 o.w.
- \( P'' = \alpha P' + (1-\alpha)uv^T \), where \( u \) is the vector of all 1s
Pagerank history

• Huge advantage for Google in the early days
  – It gave a way to get an idea for the value of a page, which was useful in many different ways
    • Put an order to the web.
  – After a while it became clear that the anchor text was probably more important for ranking
  – Also, link spam became a new (dark) art
• Flood of research
  – Numerical analysis got rejuvenated
  – Huge number of variations
  – Efficiency became a great issue.
  – Huge number of applications in different fields
    • Random walk is often referred to as PageRank.
THE HITS ALGORITHM
The HITS algorithm

• Another algorithm proposed around the same time as Pagerank for using the hyperlinks to rank pages
  – Kleinberg: then an intern at IBM Almaden
  – IBM never made anything out of it
Query dependent input

Root set obtained from a text-only search engine

Root Set

**Root Set**

**OUT**
Hubs and Authorities [K98]

- Authority is not necessarily transferred directly between authorities
- Pages have double identity
  - hub identity
  - authority identity
- Good hubs point to good authorities
- Good authorities are pointed by good hubs
Hubs and Authorities

• Two kind of weights:
  – Hub weight
  – Authority weight

• The hub weight is the sum of the authority weights of the authorities pointed to by the hub

• The authority weight is the sum of the hub weights that point to this authority.
HITS Algorithm

• Initialize all weights to 1.
• Repeat until convergence
  – $O$ operation: hubs collect the weight of the authorities
    \[ h_i = \sum_{j:i \rightarrow j} a_j \]
  – $I$ operation: authorities collect the weight of the hubs
    \[ a_i = \sum_{j:j \rightarrow i} h_j \]
  – Normalize weights under some norm
HITS and eigenvectors

- The HITS algorithm is a power-method eigenvector computation.
- In vector terms:
  - $a^t = A^T h^{t-1}$ and $h^t = A a^{t-1}$
  - $a^t = A^T A a^{t-1}$ and $h^t = A A^T h^{t-1}$
  - Repeated iterations will converge to the eigenvectors.
- The authority weight vector $a$ is the eigenvector of $A^T A$ and the hub weight vector $h$ is the eigenvector of $A A^T$.
- The vectors $a$ and $h$ are called the singular vectors of the matrix $A$. 
Singular Value Decomposition

\[ A = U \Sigma V^T = \begin{bmatrix} \tilde{u}_1 & \tilde{u}_2 & \cdots & \tilde{u}_r \end{bmatrix} \begin{bmatrix} \sigma_1 &  &  &  \\ & \sigma_2 &  &  \\ &  & \ddots &  \\ &  &  & \sigma_r \end{bmatrix} \begin{bmatrix} \tilde{v}_1 \\ \tilde{v}_2 \\ \vdots \\ \tilde{v}_r \end{bmatrix} \]

- \( r \) : rank of matrix \( A \)
- \( \sigma_1 \geq \sigma_2 \geq \ldots \geq \sigma_r \) : singular values (square roots of eig-vals \( AA^T, A^TA \))
- \( \tilde{u}_1, \tilde{u}_2, \ldots, \tilde{u}_r \) : left singular vectors (eig-vectors of \( AA^T \))
- \( \tilde{v}_1, \tilde{v}_2, \ldots, \tilde{v}_r \) : right singular vectors (eig-vectors of \( A^TA \))
- \[ A = \sigma_1 \tilde{u}_1 \tilde{v}_1^T + \sigma_2 \tilde{u}_2 \tilde{v}_2^T + \cdots + \sigma_r \tilde{u}_r \tilde{v}_r^T \]
Why does the Power Method work?

- If a matrix $R$ is real and symmetric, it has real eigenvalues and eigenvectors: $(\lambda_1, w_1), (\lambda_2, w_2), ..., (\lambda_r, w_r)$
  
  - $r$ is the rank of the matrix
  
  - $|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_r|$

- For any matrix $R$, the eigenvectors $w_1, w_2, ..., w_r$ of $R$ define a basis of the vector space
  
  - For any vector $x$, $Rx = \alpha_1 w_1 + \alpha_2 w_2 + \cdots + \alpha_r w_r$

- After $t$ multiplications we have:
  
  - $R^t x = \lambda_1^{t-1} \alpha_1 w_1 + \lambda_2^{t-1} \alpha_2 w_2 + \cdots + \lambda_r^{t-1} \alpha_r w_r$

- Normalizing leaves only the term $w_1$.
