

DATA MINING CLUSTERING

The k-means algorithm

Hierarchical Clustering

The DBSCAN algorithm

Evaluation

What is a Clustering?

A **grouping** of objects such that the objects in a **group** (**cluster**) are similar (or related) to one another and different from (or unrelated to) the objects in other groups (clusters)

Why Cluster Analysis

- **Understanding**

- **Group** related **documents** for browsing, **genes and proteins** that have similar functionality, **stocks** with similar price fluctuations, **users** with same behavior

- **Summarization**

- Reduce the size of large data sets

- **Applications**

- Recommendation systems
- Search Personalization

	<i>Discovered Clusters</i>	<i>Industry Group</i>

Clustering precipitation
in Australia

Early applications of cluster analysis

- John Snow, London 1854

Figure 1.1: Plotting cholera cases on a map of London

Types of Clusterings

- Important distinction between **hierarchical** and **partitional** sets of clusters
- **Partitional** Clustering
 - A division data objects into subsets (**clusters**) such that each data object is in exactly one subset
- **Hierarchical** clustering
 - A set of nested clusters organized as a hierarchical tree

Partitional Clustering

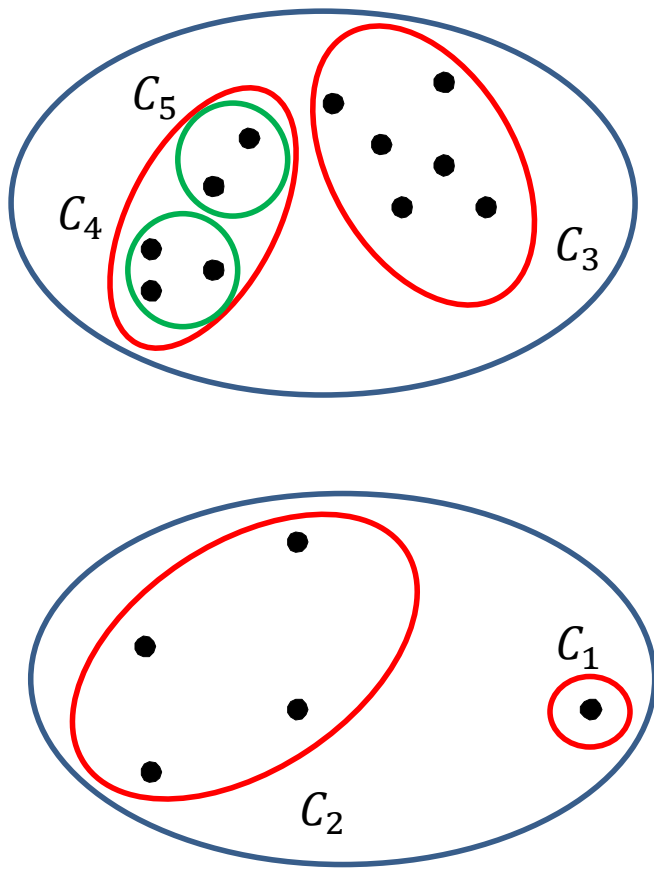

Original Points

A Partitional Clustering

Hierarchical Clustering

Hierarchical Clustering

Hierarchical Clustering dendrogram

Other types of clustering

- **Exclusive** (or **non-overlapping**) versus **non-exclusive** (or **overlapping**)
 - In non-exclusive clusterings, points may belong to multiple clusters.
 - Points that belong to multiple classes, or 'border' points
- **Fuzzy** (or **soft**) versus **non-fuzzy** (or **hard**)
 - In fuzzy clustering, a point belongs to every cluster with some weight between 0 and 1
 - Weights usually must sum to 1 (often interpreted as **probabilities**)
- **Partial** versus **complete**
 - In some cases, we only want to cluster some of the data

Clustering objectives

- Well-Separated Clusters:
 - A cluster is a set of points such that any point in a cluster is closer (or more similar) to every other point in the cluster than to any point not in the cluster.

3 well-separated clusters

Clustering objectives

- Center-based Clusters:

- A cluster is a set of objects such that an object in a cluster is **closer** (more **similar**) to the “center” of a cluster, than to the center of any other cluster
- The center of a cluster is often a **centroid**, the minimizer of distances from all the points in the cluster, or a **medoid**, the most “representative” point of a cluster

4 center-based clusters

Clustering objectives

- **Contiguous Clusters** (Nearest neighbor or Transitive)
 - A cluster is a set of points such that a point in a cluster is closer (or more similar) to one or more other points in the cluster than to any point not in the cluster.

8 contiguous clusters

Clustering Objectives

- Density-based clusters

- A cluster is a dense region of points, which is separated by low-density regions, from other regions of high density.
- Used when the clusters are irregular or intertwined, and when noise and outliers are present.

6 density-based clusters

Clustering objectives

- Shared Property or Conceptual Clusters
 - Finds clusters that share some common property or represent a particular concept.

A cluster is defined as a set of points that lie on a circle

Clustering objectives

- Clustering as an **optimization problem**
 - Finds clusters that minimize or maximize an **objective function**.
 - Consider all possible ways of dividing the points into clusters and compute the '**goodness**' of each clustering using the objective function to find the best one.
 - Usually, finding the best is NP-hard (no polynomial algorithm).
 - Can have **global** or **local** objectives.
 - Hierarchical clustering algorithms typically have local objectives
 - Partitional algorithms typically have global objectives
 - A variation of the global objective function approach is to **fit** the data to a **parameterized (probabilistic) model**.
 - The **parameters** for the model are determined from the data, and they determine the clustering
 - E.g., **Mixture models** assume that the data is a 'mixture' of a number of statistical distributions.

Clustering Algorithms

- K-means and its variants
- Hierarchical clustering
- DBSCAN

K-MEANS

K-means Clustering

- Partitional clustering approach
- Each cluster is associated with a **centroid** (center point)
- Each point is assigned to the cluster with the **closest** centroid
- Number of clusters, **K**, must be specified
- The **objective** is to:
 - find **K centroids** and
 - the **assignment** of **points to clusters/centroids**
 - so as to **minimize the sum of distances** of the points to their respective **centroid**

K-means Clustering as an optimization problem

- **Problem:** Given a set X of n objects and an integer K , find a grouping of the points into K clusters $C = \{C_1, C_2, \dots, C_K\}$ with centroids $\{c_1, c_2, \dots, c_K\}$ that **minimizes** the cost function

$$Cost(C) = \sum_{i=1}^K \sum_{x \in C_i} dist(x, c_i)$$

Definition for a general distance function *dist*

- Note: We need to find **both** the **grouping** into clusters **and** the **centroids** per cluster.

K-means Clustering

- Most common definition is with euclidean distance, minimizing the **Sum of Squares Error (SSE)** – distance function
 - Sometimes K-means clustering is defined like that
- **Problem:** Given a set X of n points in a d -dimensional space and an integer K group the points into K clusters $C = \{C_1, C_2, \dots, C_K\}$ such that

$$Cost(C) = \sum_{i=1}^K \sum_{x \in C_i} (x - c_i)^2$$

Sum of Squares Error (SSE)

is **minimized**, where c_i is the **mean** of the points in cluster C_i

Complexity of the k-means problem

- **NP-hard** if the dimensionality of the data is at least 2 ($d \geq 2$)
 - Finding the best solution in polynomial time is infeasible
- For $d = 1$ the problem is solvable in polynomial time (how?)
- A simple iterative algorithm works quite well in practice

K-means Algorithm

- Also known as **Lloyd's algorithm**.
- K-means is sometimes synonymous with this algorithm

1. Select K points as the **initial centroids**
2. **repeat**
3. Form K clusters by assigning each point to the closest centroid
4. Compute the new **centroid*** of each cluster
5. **until** The centroids do not change

*The centroid of a set of points is the point that minimizes the sum of distances from the points in the set

Example

Example

K-means Algorithm – Initialization

- Initial centroids are often chosen randomly.
 - Clusters produced vary from one run to another.

Two different K-means Clusterings

Optimal Clustering

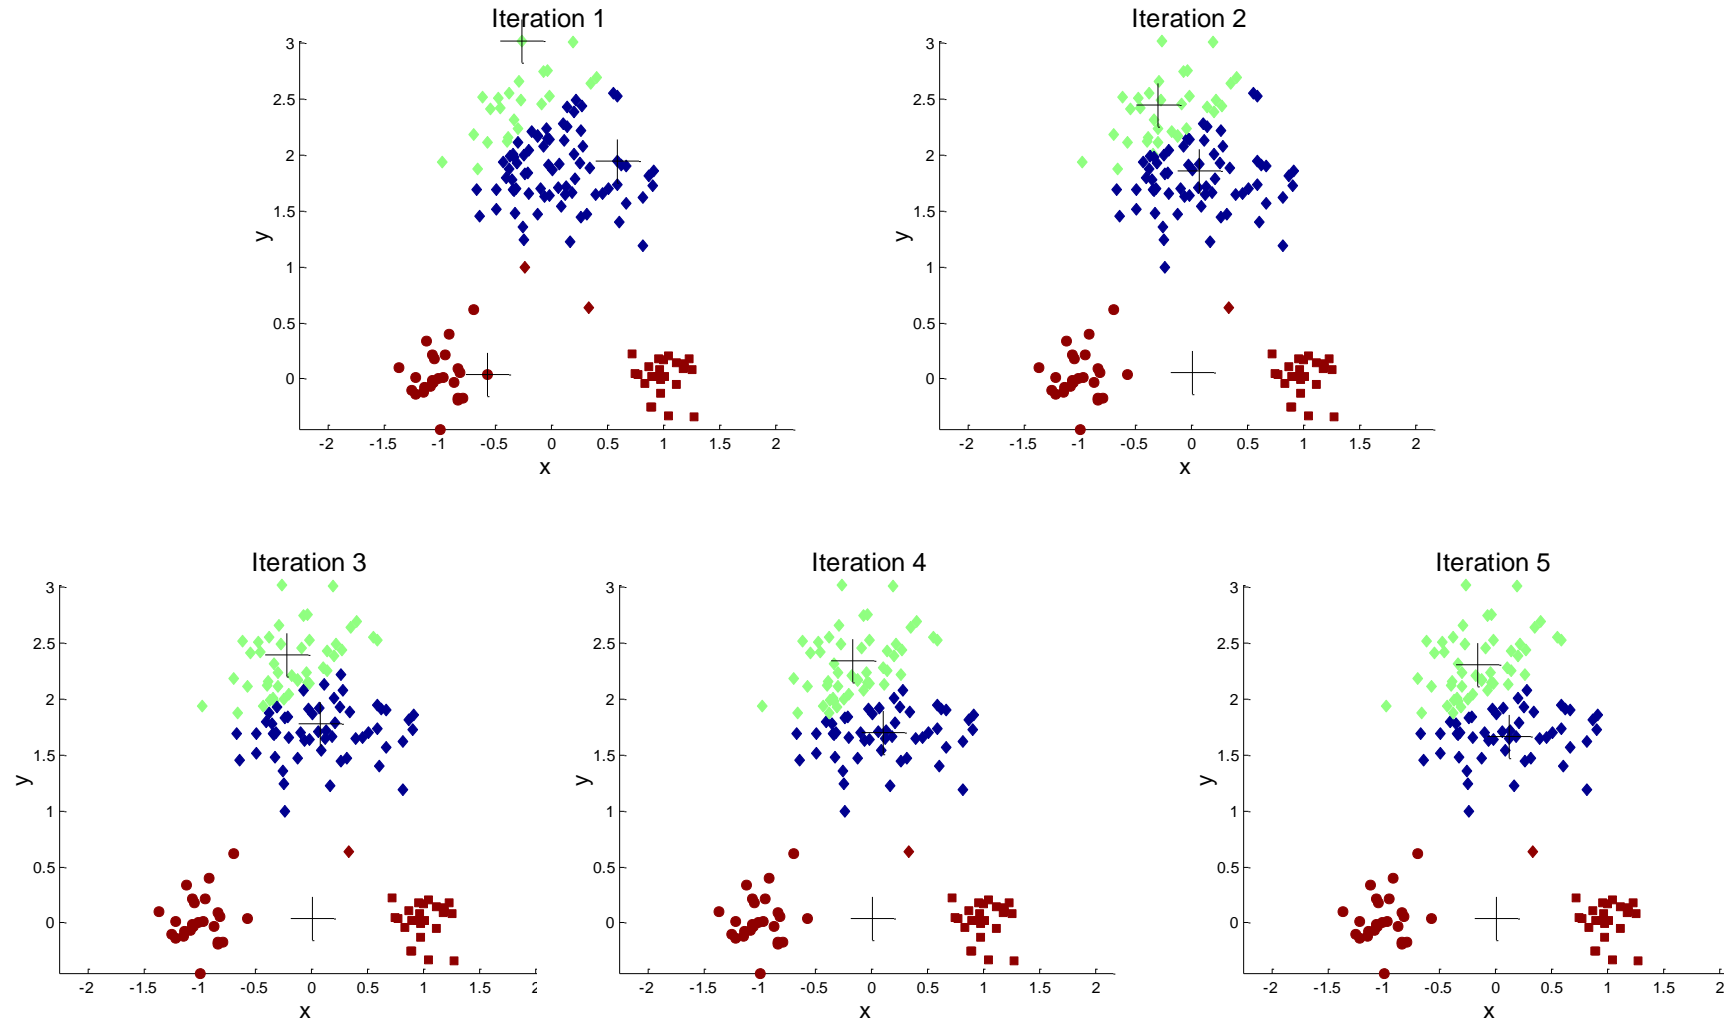

Sub-optimal Clustering

Importance of Choosing Initial Centroids

Importance of Choosing Initial Centroids ...

Dealing with Initialization

- Do **multiple runs** and select the clustering with the smallest error
- Select original set of points by methods other than random.
E.g., pick the most distant (from each other) points as cluster centers (**K-means++** algorithm)

K-means Algorithm – Centroids

- ‘**Closeness**’ is measured by some similarity or distance function
 - E.g., Euclidean distance (SSE), cosine similarity, correlation, etc.
- The **centroid** depends on the distance function
 - The **minimizer** for the distance function
- **Centroid**:
 - The **mean** of the points in the cluster for SSE, and cosine similarity
 - The **median** for Manhattan distance.
- Finding the centroid is not always easy
 - It can be an NP-hard problem for some distance functions
 - E.g., median for multiple dimensions

K-means Algorithm – Convergence

- K-means will **converge** for common similarity measures mentioned above.
 - Most of the convergence happens in the first few iterations.
 - Often the stopping condition is changed to ‘**Until relatively few points change clusters**’
- Complexity is $O(n \cdot K \cdot I \cdot d)$
 - n = number of points,
 - K = number of clusters,
 - I = number of iterations,
 - d = dimensionality
- In general, a fast and efficient algorithm

Limitations of K-means

- K-means has problems when clusters are of different:
 - sizes
 - densities
 - non-globular shapes
- K-means has problems when the data contains outliers.

Limitations of K-means: Differing Sizes

Original Points

K-means (3 Clusters)

Limitations of K-means: Differing Density

Original Points

K-means (3 Clusters)

Limitations of K-means: Non-globular Shapes

Original Points

K-means (2 Clusters)

Overcoming K-means Limitations

Original Points

K-means Clusters

One solution is to use many clusters.
Find parts of clusters, but need to put together.

Overcoming K-means Limitations

Original Points

K-means Clusters

Overcoming K-means Limitations

Original Points

K-means Clusters

Variations

- **K-medoids**: Similar problem definition as in K-means, but the centroid of the cluster is defined to be one of the points in the cluster (the **medoid**).
- **K-centers**: Similar problem definition as in K-means, but the goal now is to minimize the maximum **diameter** of the clusters
 - diameter of a cluster is maximum distance between any two points in the cluster.

HIERARCHICAL CLUSTERING

Hierarchical Clustering

- Two main types of hierarchical clustering
 - **Agglomerative:**
 - Start with the points as individual clusters
 - At each step, merge the closest pair of clusters until only one cluster (or k clusters) left
 - **Divisive:**
 - Start with one, all-inclusive cluster
 - At each step, split a cluster until each cluster contains a point (or there are k clusters)
- Traditional hierarchical algorithms use a **similarity** or **distance matrix**
 - Merge or split one cluster at a time

Hierarchical Clustering

- Produces a set of nested clusters organized as a hierarchical tree
- Can be visualized as a **dendrogram**
 - A tree like diagram that records the sequences of merges or splits

Strengths of Hierarchical Clustering

- Do not have to assume any particular number of clusters
 - Any desired number of clusters can be obtained by 'cutting' the dendrogram at the proper level
- Dendrograms **may** correspond to meaningful **taxonomies**
 - Example in biological sciences (e.g., animal kingdom, phylogeny reconstruction, ...)

Agglomerative Clustering Algorithm

- Most popular hierarchical clustering technique
- Basic algorithm is straightforward
 1. Compute the **proximity matrix**
 2. Let each data point be a cluster
 3. **Repeat**
 4. **Merge** the two **closest clusters**
 5. **Update** the proximity matrix
 6. **Until** only a single cluster remains
- Key operation is the computation of the **proximity of two clusters**
 - Different approaches to defining the **distance between clusters** distinguish the different algorithms

Starting Situation

- Start with **single-point clusters** and a proximity matrix **between points**

Single Link – Complete Link

- Another way to view the processing of the hierarchical algorithm is that we create links between the **elements** in order of **increasing distance**
 - The MIN – **Single Link**, will merge two clusters when a **single pair** of elements between the two clusters is linked
 - The MAX – **Complete Linkage** will merge two clusters when **all pairs** of elements between the two clusters have been linked.

Hierarchical Clustering: MIN

Nested Clusters

	1	2	3	4	5	6
1	0	.24	.22	.37	.34	.23
2	.24	0	.15	.20	.14	.25
3	.22	.15	0	.15	.28	.11
4	.37	.20	.15	0	.29	.22
5	.34	.14	.28	.29	0	.39
6	.23	.25	.11	.22	.39	0

Dendrogram

Strength of MIN

Original Points

Two Clusters

- Can handle non-elliptical shapes

Limitations of MIN

Original Points

Two Clusters

- Sensitive to noise and outliers

Hierarchical Clustering: MAX

Nested Clusters

Dendrogram

	1	2	3	4	5	6
1	0	.24	.22	.37	.34	.23
2	.24	0	.15	.20	.14	.25
3	.22	.15	0	.15	.28	.11
4	.37	.20	.15	0	.29	.22
5	.34	.14	.28	.29	0	.39
6	.23	.25	.11	.22	.39	0

Strength of MAX

Original Points

Two Clusters

- Less susceptible to noise and outliers

Limitations of MAX

Original Points

Two Clusters

- Tends to break large clusters
- Biased towards globular clusters

Hierarchical Clustering: Group Average

Nested Clusters

	1	2	3	4	5	6
1	0	.24	.22	.37	.34	.23
2	.24	0	.15	.20	.14	.25
3	.22	.15	0	.15	.28	.11
4	.37	.20	.15	0	.29	.22
5	.34	.14	.28	.29	0	.39
6	.23	.25	.11	.22	.39	0

Dendrogram

Hierarchical Clustering: Group Average

- Compromise between Single and Complete Link
- Strengths
 - Less susceptible to noise and outliers
- Limitations
 - Biased towards globular clusters

Cluster Similarity: Ward's Method

- Similarity of two clusters is based on the increase in squared error (SSE) when two clusters are merged
 - Similar to group average if distance between points is sum of squares distance
- Hierarchical analogue of K-means
 - Can be used to initialize K-means
- Less susceptible to noise and outliers
- Biased towards globular cluster

Hierarchical Clustering: Comparison

Hierarchical Clustering: Time and Space requirements

- $O(N^2)$ space since it uses the proximity matrix.
 - N is the number of points.
- $O(N^3)$ time in many cases
 - There are N steps and at each step the size, N^2 , proximity matrix must be updated and searched
 - Complexity can be reduced to $O(N^2 \log(N))$ time for some approaches

Hierarchical Clustering: Problems and Limitations

- Computational complexity in time and space
- Once a decision is made to combine two clusters, it cannot be undone
- No objective function is directly minimized
- Different schemes have problems with one or more of the following:
 - Sensitivity to noise and outliers
 - Difficulty handling different sized clusters and convex shapes
 - Breaking large clusters

DBSCAN

DBSCAN: Density-Based Clustering

- DBSCAN is a Density-Based Clustering algorithm
- Reminder: In density-based clustering we partition points into dense regions separated by not-so-dense regions.
- Important Questions:
 - How do we measure density?
 - What is a dense region?
- DBSCAN:
 - Density at point p : number of points within a circle of radius Eps
 - Dense Region: A circle of radius Eps that contains at least $MinPts$ points

DBSCAN

- Characterization of points
 - A point is a **core point** if it has more than a specified number of points (**MinPts**) within **Eps**
 - These points belong in a **dense region** and are at the **interior** of a cluster
 - A **border point** has fewer than **MinPts** within **Eps**, but it is in the neighborhood of a **core** point.
 - A **noise point** is any point that is neither a core point nor a border point.

DBSCAN: Core, Border, and Noise Points

DBSCAN: Core, Border and Noise Points

Original Points

Point types: **core**, **border** and **noise**

Eps = 10, MinPts = 4

Density-Connected points

- Density edge
 - We place an edge between two core points q and p if they are within distance Eps .
- Density-connected
 - A point p is density-connected to a point q if there is a path of edges from p to q

DBSCAN Algorithm

- Label points as **core**, **border** and **noise**
- Eliminate **noise** points
- For every **core** point **p** that has not been assigned to a cluster
 - Create a new cluster with the point **p** and all the points that are **density-connected** to **p**.
- Assign **border** points to the cluster of the closest core point.

DBSCAN: Determining Eps and MinPts

- Idea: for points in a cluster, their k^{th} nearest neighbors are at roughly the same distance
- Noise points have the k^{th} nearest neighbor at farther distance
- So, plot sorted distance of every point to its k^{th} nearest neighbor
- Find the distance d where there is a “knee” in the curve
 - $\text{Eps} = d$, $\text{MinPts} = k$

Eps ~ 7-10
MinPts = 4

When DBSCAN Works Well

Original Points

Clusters

- Resistant to Noise
- Can handle clusters of different shapes and sizes

DBSCAN: Sensitive to Parameters

Figure 8. DBScan results for DS1 with MinPts at 4 and Eps at (a) 0.5 and (b) 0.4.

Figure 9. DBScan results for DS2 with MinPts at 4 and Eps at (a) 5.0, (b) 3.5, and (c) 3.0.

When DBSCAN Does NOT Work Well

Original Points

- Varying densities
- High-dimensional data

(MinPts=4, Eps=9.75).

(MinPts=4, Eps=9.92)

Other algorithms

- **PAM, CLARANS**: Solutions for the **k-medoids** problem
- **BIRCH**: Constructs a **hierarchical tree** that acts a summary of the data, and then clusters the leaves.
- **MST**: Clustering using the **Minimum Spanning Tree**.
- **ROCK**: clustering **categorical data** by neighbor and link analysis
- **LIMBO, COOLCAT**: Clustering **categorical data** using **information theoretic** tools.
- **CURE**: **Hierarchical** algorithm uses different representation of the cluster
- **CHAMELEON**: **Hierarchical** algorithm uses **closeness and interconnectivity** for merging

CLUSTERING EVALUATION

Clustering Evaluation

- We need to evaluate the “goodness” of the resulting clusters?
- But “clustering lies in the eye of the beholder”!

Quality of Clustering can be Ambiguous

How many clusters?

Six Clusters

Two Clusters

Four Clusters

Clustering Evaluation

- Then why do we want to evaluate them?
 - To avoid finding patterns in noise
 - To compare clusterings, or clustering algorithms
 - To compare against a “ground truth”

Different Aspects of Cluster Validation

1. **Internal Evaluation:** Evaluating how well the results of a cluster analysis fit the data *without* reference to external information.
 - Use only the data
2. Determining the **clustering tendency** of a set of data, i.e., distinguishing whether non-random structure actually exists in the data.
3. Determining the **'correct' number of clusters**.
4. **External Evaluation:** Comparing the results of a cluster analysis to externally known results, e.g., to externally given **class labels**.

Metrics for cluster and clustering validity

- For the following we will see some metrics for the clustering validity.
- The metrics can be applied for the evaluation of either a **cluster**, or a **clustering**
- In **cluster validity**, we **evaluate a group of points**, as to whether they were correctly placed together.
 - We usually check if the group is homogeneous (for some notion of homogeneity)
- In **clustering validity**, we **evaluate a collection of clusters**
 - We often use the (weighted) average of cluster validity
 - There are also metrics that look at the relationships between the clusters, e.g., how well-separated the clusters are.

CLUSTER VALIDITY WITH INTERNAL CRITERIA

Internal Measures

- **Internal Index:** A metric used to measure the goodness of a clustering structure without reference to external information
 - Example: Sum of Square Errors (SSE)
- SSE can be used to **evaluate** a cluster or a clustering:
 - For a cluster of points C_i , the SSE is:

$$SSE(C_i) = \sum_{x \in C_i} (x - c_i)^2, c_i = \text{centroid of cluster } C_i$$

- For a clustering $C = \{C_1, C_2, \dots, C_k\}$, the SSE is:

$$SSE(C) = \sum_i \sum_{x \in C_i} (x - c_i)^2, c_i = \text{centroid of cluster } C_i$$

- SSE can also be used to **compare** clusters, or clusterings

Cohesion and Separation

- In general, we evaluate clusters and clusterings based on **cohesion** and **separation**
 - **Cluster Cohesion**: Measures how closely related are objects in a cluster
 - **Cluster Separation**: Measure how distinct or well-separated a cluster is from other clusters

- Example: Squared Error

- **Cohesion** is measured by the **within cluster sum of squares** (SSE)

$$WSS = \sum_i \sum_{x \in C_i} (x - c_i)^2$$

We want this to be small

- **Separation** is measured by the **sum of square error of the centroids**

$$BSS = \sum_i m_i (c - c_i)^2$$

We want this to be large

- Where m_i is the size of cluster i , c the **overall mean**. It also holds that:

$$BSS = \sum_{x \in C_i} \sum_{y \in C_j} (x - y)^2$$

- Interesting observation: $WSS + BSS = \text{constant}$

Cohesion and Separation

- A **proximity-graph**-based approach can also be used for cohesion and separation.
 - Cluster cohesion is the sum of the weight of all links within a cluster.
 - Cluster separation is the sum of the weights between nodes in the cluster and nodes outside the cluster.

cohesion

separation

Silhouette Coefficient

- Silhouette Coefficient combines ideas of both cohesion and separation, for **individual points**, as well as **clusters** and **clusterings**
- Given a clustering, for an individual **point i**
 - Calculate **a_i** = average distance of i to the points in its own cluster
 - Calculate **b_i** = min (over clusters) of the average distance of i to points in another cluster
 - The silhouette coefficient for a **point i** is then given by

$$s_i = 1 - a_i/b_i$$

- Typically, between 0 and 1, the closer to 1 the better.
 - Can be less than 0 but this is a problematic case
- For a **cluster/clustering**: Calculate the **average** Silhouette Coefficient of the points in a cluster, or overall, for the clustering

Silhouette Coefficient Example

Figure 8.29. Silhouette coefficients for points in ten clusters.

Measuring Cluster Validity Via Correlation

■ Two matrices

■ Similarity or Distance Matrix

- One row and one column for each data point
- An entry is the **similarity or distance** of the associated pair of points

■ “Incidence” Matrix

- One row and one column for each data point
- An entry is **1** if the associated pair of points belong to the **same cluster**
- An entry is **0** if the associated pair of points belongs to **different clusters**

$$D = \begin{bmatrix} A & B & C & D \\ 0 & 0.9 & 2.2 & 1.5 \\ 0.9 & 0 & 1.2 & 1.7 \\ 2.2 & 1.2 & 0 & 1.1 \\ 1.5 & 1.7 & 1.1 & 0 \end{bmatrix} \begin{matrix} A \\ B \\ C \\ D \end{matrix}$$

$$I = \begin{bmatrix} A & B & C & D \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix} \begin{matrix} A \\ B \\ C \\ D \end{matrix}$$

Measuring Cluster Validity Via Correlation

- Compute the **correlation** between the two matrices

$$\text{CorrCoeff}(X, Y) = \frac{\sum_i (x_i - \mu_X)(y_i - \mu_Y)}{\sqrt{\sum_i (x_i - \mu_X)^2} \sqrt{\sum_i (y_i - \mu_Y)^2}}$$

- Since the matrices are symmetric, only the correlation between $n(n-1) / 2$ entries needs to be calculated.
- **High** correlation (**positive** for similarity, **negative** for distance) indicates that points that belong to the same cluster are close to each other.
- Not a good measure for some density or contiguity-based clusters.

$$S = \begin{matrix} & \begin{matrix} A & B & C & D \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \end{matrix} & \begin{bmatrix} 0 & 0.9 & 2.2 & 1.5 \\ 0.9 & 0 & 1.2 & 1.7 \\ 2.2 & 1.2 & 0 & 1.1 \\ 1.5 & 1.7 & 1.1 & 0 \end{bmatrix} \end{matrix}$$

$$I = \begin{matrix} & \begin{matrix} A & B & C & D \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \end{matrix} & \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix} \end{matrix}$$

$$\begin{aligned} &\text{CorrCoeff}([0.9, 2.2, 1.5, 1.2, 1.7, 1.1], \\ &\quad [1, 0, 0, 0, 0, 1]) \\ &= -0.71 \end{aligned}$$

Using Similarity Matrix for Cluster Validation

- Order the **similarity** matrix with respect to cluster labels and inspect visually.

Corr = -0.9235

$$sim(i,j) = 1 - \frac{d_{ij} - d_{min}}{d_{max} - d_{min}}$$

Using Similarity Matrix for Cluster Validation

- Clusters in random data are not so crisp

Corr = -0.5810

K-means

Using Similarity Matrix for Cluster Validation

DBSCAN

- Clusters in more complicated figures are not well separated
- This technique can only be used for small datasets since it requires a quadratic computation

Internal measures – caveats

- Internal measures have the problem that the clustering algorithm **did not set out to optimize this measure**, so it will not necessarily do well with respect to the measure.
 - Essentially, we check whether one criterion correlates well with another
- An internal measure can also be used as an **objective function** for clustering
 - The algorithm that optimizes this criterion is expected to do well, so this is not so interesting.
- We cannot win!

STATISTICAL FRAMEWORK FOR CLUSTER(ING) VALIDITY

Framework for Cluster Validity

- Need a **framework** to interpret any measure.
 - For example, if our measure of evaluation has the value, 10, is that good, fair, or poor?
- **Statistics** provide a framework for cluster validity
 - The more “**non-random**” a clustering result is, the more likely it represents valid structure in the data
 - Compare the index value for a clustering with the values of the index that result from **clustering random data**, or from **random clusterings**.
 - If the value of the index is **unlikely**, then the clustering results are valid
 - Comparing against clustering of random data tells us if there is valid clustering structure in the data
 - Comparing against random clusterings tells us if the clustering algorithm is meaningful
 - Although a random clustering is a weak alternative.
- For comparing the results of two different clusterings, a framework is less necessary, but we may want to know whether the difference between two index values is **significant**

Statistical Framework for SSE

- Example

- Compare SSE of 0.005 against three clusters in random data
- Histogram of SSE for three clusters in 500 random data sets of 100 random points distributed in the range 0.2 – 0.8 for x and y
 - Value 0.005 is very unlikely

Statistical Framework for Correlation

- Correlation of incidence and proximity matrices for the K-means clusterings of the following two data sets.

Corr = -0.9235

Corr = -0.5810

Empirical p-value

- What we do is similar to a **permutation test**:
- We have a **measurement** v (e.g., the SSE value)
- We compute N measurements on **random datasets**
- We compute the **empirical p-value** as the **fraction** of measurements in the random data that have value **less or equal** than value v (or greater or equal if we want to maximize)
 - i.e., the value in the random dataset is **at least as good** as that in the real data
- We usually require that **$p\text{-value} \leq 0.05$**
- **Hard question**: what is the right notion of a random dataset?

ESTIMATING THE “RIGHT” NUMBER OF CLUSTERS

Estimating the “right” number of clusters

- Typical approach: find a “knee” in an internal measure curve.

- Question: why not the k that **minimizes** the SSE?
 - More advanced: minimize a measure, but with a “**simple**” clustering
- **Desirable property**: the clustering algorithm does not require the number of clusters to be specified (e.g., DBSCAN)

Estimating the “right” number of clusters

- SSE curve for a more complicated data set

SSE of clusters found using K-means

Estimating the “right” number of clusters

- A metric that is better suited for this task is the **average silhouette coefficient** which does not change monotonically with the number of clusters
- In this example 6 seems to be a good number of clusters since it has high silhouette coefficient and low SSE
- 2 has the highest silhouette coefficient but highest SSE.
- 12 could be another alternative

EVALUATION WITH EXTERNAL “GROUND TRUTH”

External Measures for Clustering Validity

- Assume that the data is **labeled** with some class labels
 - E.g., **documents** are classified into **topics**, **people** classified according to their **income**, **politicians** classified according to the **political party**.
 - This is called the “**ground truth**”
- In this case we want the clusters to be **homogeneous** with respect to classes
 - **Each cluster** should contain elements of **mostly one class**
 - **Each class** should ideally be assigned to a **single cluster**
- This does not always make sense
 - **Clustering** is not the same as **classification**
 - ...but this is what people use most of the time

Confusion/Contingency matrix

- Rows: clusters
- Columns: classes
- Entries: counts/probability of cluster-class pair
- n = number of points
- m_i = points in cluster i
- c_j = points in class j
- n_{ij} = points in cluster i coming from class j
- The confusion/contingency matrix is sometimes used for evaluation as is
 - It gives us the mapping between the clusters and ground truth classes

Confusion/Contingency matrix of clusters and classes (counts)

	Class 1	Class 2	Class 3	
Cluster 1	n_{11}	n_{12}	n_{13}	m_1
Cluster 2	n_{21}	n_{22}	n_{23}	m_2
Cluster 3	n_{31}	n_{32}	n_{33}	m_3
	c_1	c_2	c_3	n

Example

	Class 1	Class 2	Class 3	
Cluster 1	2	3	85	90
Cluster 2	90	12	8	110
Cluster 3	8	85	7	100
	100	100	100	300

Measures of cluster homogeneity

- Compute probabilities:

$$p_{ij} = \frac{n_{ij}}{m_i}$$

- The probability that a randomly selected point from cluster i comes from class j .
- Probabilities of rows sum to 1

- **Purity:**

- Of a cluster i : $p_i = \max_j p_{ij}$
- Of a clustering: $p(C) = \sum_{i=1}^K \frac{m_i}{n} p_i$

- **Entropy:**

- Of a cluster i : $e_i = -\sum_{j=1}^L p_{ij} \log p_{ij}$
 - Highest when uniform, zero when single class
- Of a clustering: $e = \sum_{i=1}^K \frac{m_i}{n} e_i$

	Class 1	Class 2	Class 3	
Cluster 1	p_{11}	p_{12}	p_{13}	m_1
Cluster 2	p_{21}	p_{22}	p_{23}	m_2
Cluster 3	p_{31}	p_{32}	p_{33}	m_3
	c_1	c_2	c_3	n

	Class 1	Class 2	Class 3	
Cluster 1	0.02	0.03	0.95	90
Cluster 2	0.82	0.11	0.07	110
Cluster 3	0.08	0.85	0.07	100
	100	100	100	300

Purity: (0.94, 0.81, 0.85)
– overall 0.86

Entropy: (0.33, 0.85, 0.76)
– overall 0.66

Precision-recall for cluster-class combinations

- **Precision** of **cluster i** with respect to **class j** : $Prec(i, j) = \frac{n_{ij}}{m_i} = p_{ij}$
 - Percentage of the **cluster i** that comes from **class j**
- **Recall** of **cluster i** with respect to **class j** : $Rec(i, j) = \frac{n_{ij}}{c_j}$
 - Percentage of **class j** that goes to **cluster i**

	Class 1	Class 2	Class 3	
Cluster 1	2	3	85	90
Cluster 2	90	12	8	110
Cluster 3	8	85	7	100
	100	100	100	300

	Class 1	Class 2	Class 3
Cluster 1	0.02	0.03	0.95
Cluster 2	0.82	0.11	0.07
Cluster 3	0.08	0.85	0.07

Precision Table

	Class 1	Class 2	Class 3
Cluster 1	0.02	0.03	0.85
Cluster 2	0.90	0.12	0.08
Cluster 3	0.08	0.85	0.07

Recall Table

Precision/Recall for clusters and clusterings

- Assign to cluster i the class k_i such that $k_i = \arg \max_j n_{ij}$

- Precision:**

- Of cluster i : $Prec(i) = \frac{n_{ik_i}}{m_i}$
- Of the clustering: $Prec(C) = \sum_i \frac{m_i}{n} Prec(i)$

- Recall:**

- Of cluster i : $Rec(i) = \frac{n_{ik_i}}{c_{k_i}}$
- Of the clustering: $Rec(C) = \sum_i \frac{m_i}{n} Rec(i)$

- F-measure:**

- Harmonic Mean of Precision and Recall

	Class 1	Class 2	Class 3	
Cluster 1	2	3	85	90
Cluster 2	90	12	8	110
Cluster 3	8	85	7	100
	100	100	100	300

Precision: (0.94, 0.81, 0.85)

– overall 0.86

Recall: (0.85, 0.9, 0.85)

- overall 0.87

Good and bad clustering

	Class 1	Class 2	Class 3	
Cluster 1	2	3	85	90
Cluster 2	90	12	8	110
Cluster 3	8	85	7	100
	100	100	100	300

Purity: (0.94, 0.81, 0.85)

– overall 0.86

Precision: (0.94, 0.81, 0.85)

– overall 0.86

Recall: (0.85, 0.9, 0.85)

- overall 0.87

	Class 1	Class 2	Class 3	
Cluster 1	20	35	35	90
Cluster 2	30	42	38	110
Cluster 3	38	35	27	100
	100	100	100	300

Purity: (0.38, 0.38, 0.38)

– overall 0.38

Precision: (0.38, 0.38, 0.38)

– overall 0.38

Recall: (0.35, 0.42, 0.38)

– overall 0.39

Another clustering

	Class 1	Class 2	Class 3	
Cluster 1	0	0	35	35
Cluster 2	50	77	38	165
Cluster 3	38	35	27	100
	100	100	100	300

Cluster 1:
Purity: 1
Precision: 1
Recall: 0.35

External Measures of Cluster Validity: Entropy and Purity

Table 5.9. K-means Clustering Results for LA Document Data Set

Cluster	Entertainment	Financial	Foreign	Metro	National	Sports	Entropy	Purity
1	3	5	40	506	96	27	1.2270	0.7474
2	4	7	280	29	39	2	1.1472	0.7756
3	1	1	1	7	4	671	0.1813	0.9796
4	10	162	3	119	73	2	1.7487	0.4390
5	331	22	5	70	13	23	1.3976	0.7134
6	5	358	12	212	48	13	1.5523	0.5525
Total	354	555	341	943	273	738	1.1450	0.7203

entropy For each cluster, the class distribution of the data is calculated first, i.e., for cluster j we compute p_{ij} , the ‘probability’ that a member of cluster j belongs to class i as follows: $p_{ij} = m_{ij}/m_j$, where m_j is the number of values in cluster j and m_{ij} is the number of values of class i in cluster j . Then using this class distribution, the entropy of each cluster j is calculated using the standard formula $e_j = \sum_{i=1}^L p_{ij} \log_2 p_{ij}$, where the L is the number of classes. The total entropy for a set of clusters is calculated as the sum of the entropies of each cluster weighted by the size of each cluster, i.e., $e = \sum_{j=1}^K \frac{m_j}{m} e_j$, where m_j is the size of cluster j , K is the number of clusters, and m is the total number of data points.

purity Using the terminology derived for entropy, the purity of cluster j , is given by $purity_j = \max_i p_{ij}$ and the overall purity of a clustering by $purity = \sum_{j=1}^K \frac{m_j}{m} purity_j$.

Final Comment on Cluster Validity

“The validation of clustering structures is the most difficult and frustrating part of cluster analysis.

Without a strong effort in this direction, cluster analysis will remain a black art accessible only to those true believers who have experience and great courage.”

Algorithms for Clustering Data, Jain and Dubes
